NCCN Guidelines Version 2.2022

Testicular Cancer

Updates in Version 2.2022 of the NCCN Guidelines for Testicular Cancer from Version 1.2022 include:

[MS-1](#)

The Discussion section has been updated to reflect the changes in the algorithm.

Updates in Version 1.2022 of the NCCN Guidelines for Testicular Cancer from Version 2.2021 include:

[TEST-1](#)

- Footnote a modified: Though rare, when a patient presents with rapidly increasing beta-hCG or AFP and symptoms related to disseminated disease with a testicular mass, chemotherapy can be initiated immediately without waiting for a biopsy diagnosis or performing orchiectomy. *However, orchiectomy should be performed at completion of chemotherapy.*

[TEST-2](#)

- Footnote removed: With contrast.
- Footnote j modified: Elevated values should be followed after orchiectomy with repeated determination to allow precise staging. Follow declining markers until normalization or plateau nadir. (Also for Test-6)
- Footnote l modified: Eg, beta-hCG >5000 IU/L, non-pulmonary visceral metastases, or extensive lung metastasis, *or neurologic symptoms present.*

[TEST-4](#)

- Primary Treatment:
 - Modified: Primary chemotherapy (preferred)

[TEST-5](#)

- Post Chemotherapy Management
 - Modified: Repeat PET/CT or CT scan in 6–8 weeks
- Follow-Up
 - Modified: Consider 2 cycles adjuvant chemotherapy

[TEST-7](#)

- Footnote oo added: Recommend referral to a high-volume centers ~~should be considered.~~ (Also for TEST-8 and TEST-9)

[TEST-8](#)

- Footnote pp modified: RPLND is preferred as primary treatment for *stage II tumors with somatic type malignancy* ~~stage II tumors with (previously referred to as transformed teratoma) and should be considered for stage II tumors with teratoma predominance in patients with normal markers.~~
- Footnote added: RPLND should be considered for stage II tumors with teratoma predominance in patients with normal markers.

- Footnote rr added to page and modified: Patients who are at higher risk for bleomycin-related complications. *Bleomycin-based regimens should not be given to patients >50 years of age, those at increased risk for pulmonary complications, those with underlying lung disease, etc.* (Also for TEST-9, -10, and -11)

[TEST-9](#)

- Modified: Negative markers, no mass <1 cm (transaxial long axis) on CT scan
- Modified: Negative markers, no mass ≥1 cm (transaxial long axis) on CT scan
- Footnote added: Craniocaudal axis should not be used.
- Footnote removed: Referral to high-volume centers should be considered for surgical resection of masses post-chemotherapy.

[TEST-10](#)

- Postsurgical Management:
 - Surveillance (preferred) or Chemotherapy:
 - ◊ Removed: BEP for 2 cycles or
 - Chemotherapy (preferred):
 - ◊ Removed: BEP for 2 cycles or
- pN1, pN2:
 - Removed: Other Recommended Regimens; BEP=Bleomycin/etoposide/cisplatin
- Footnote uu added: This is a rare circumstance. BEP for 2 cycles is an option.

[TEST-11](#)

- Primary Treatment
 - Modified: Primary chemotherapy for *poor-risk* disease ± RT ± surgery, if clinically indicated.
- Footnote vv modified: To assess response after treatment, CT with contrast of chest/abdomen/pelvis and any other sites of disease is recommended. *PET has no role in assessing treatment response and residual masses following chemotherapy in patients with nonseminoma.* (Also for TEST-13, -14, and -15)

[Continued](#)

UPDATES

NCCN Guidelines Version 2.2022

Testicular Cancer

Updates in Version 1.2022 of the NCCN Guidelines for Testicular Cancer from Version 2.2021 include:

TEST-12

- Footnote xx added: Consider brain imaging and testicular ultrasound in patients with elevated or rising markers after primary or secondary chemotherapy to evaluate for occult brain metastases or contralateral primary disease.

TEST-15

- Third-Line Therapy:
 - ▶ Modified: MSI/MMR or TMB testing if progression after high-dose

TEST-A 1 of 2

- Table 1, Abdominal ± Pelvic ± CT:
 - ▶ Modified Year 1: At 3, 4–6, and 12 mo.
- Footnote e modified: ~~In select circumstances, a~~ An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include all the nodes that need to be assessed. ~~The same imaging modality (CT or MRI) should be used throughout surveillance.~~

TEST-A 2 of 2

- Table 3, Abdominal ± Pelvic CT:
 - ▶ Modified Year 1: At 3 mo, then at 6–12 mo or 12 mo

TEST-B 1 of 3

- Table 5, Chest x-ray:
 - ▶ Modified Year 5: *Annually As clinically indicated*
- Footnote d modified: ~~In select circumstances, a~~ An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include all the nodes that need to be assessed. ~~The same imaging modality (CT or MRI) should be used throughout surveillance.~~ (Also for TEST-B 2 of 3 and 3 of 3)

TEST-B 2 of 3

- Footnote k revised: For patients with ~~unresectable~~ *unresected* residual masses or resected residual masses containing viable cancer.
- Footnote l added: Consider annual tumor markers for years 5–10.

TEST-C 1 of 5

Second bullet modified: As a result, the risk of second cancers arising in the kidneys, liver, or bowel may be lower with 3D-CRT than IMRT, and IMRT is not recommended *necessary*.

TEST-D

- Footnote b added: Newer risk model to give prognostic information can be used through nomogram: <https://eortc.shinyapps.io/IGCCCG-Update/> (Gillesen S, et al. J Clin Oncol 2021;39:1563-1574).
- Footnote d added: Patients with good-risk disseminated seminoma with an LDH >2.5 x ULN have a worse prognosis than other good-risk patients. However, there are insufficient data at this time to recommend treating these patients differently based on LDH.

TEST-G 1 of 3

- Footnote added: Tumor mutational burden-high (TMB-H) [≥10 mutations/megabase (mut/Mb)] tumors, as determined by a validated and/or FDA-approved CGP assay. (Also for TEST-G 2 of 3)

Test-H 1 of 2

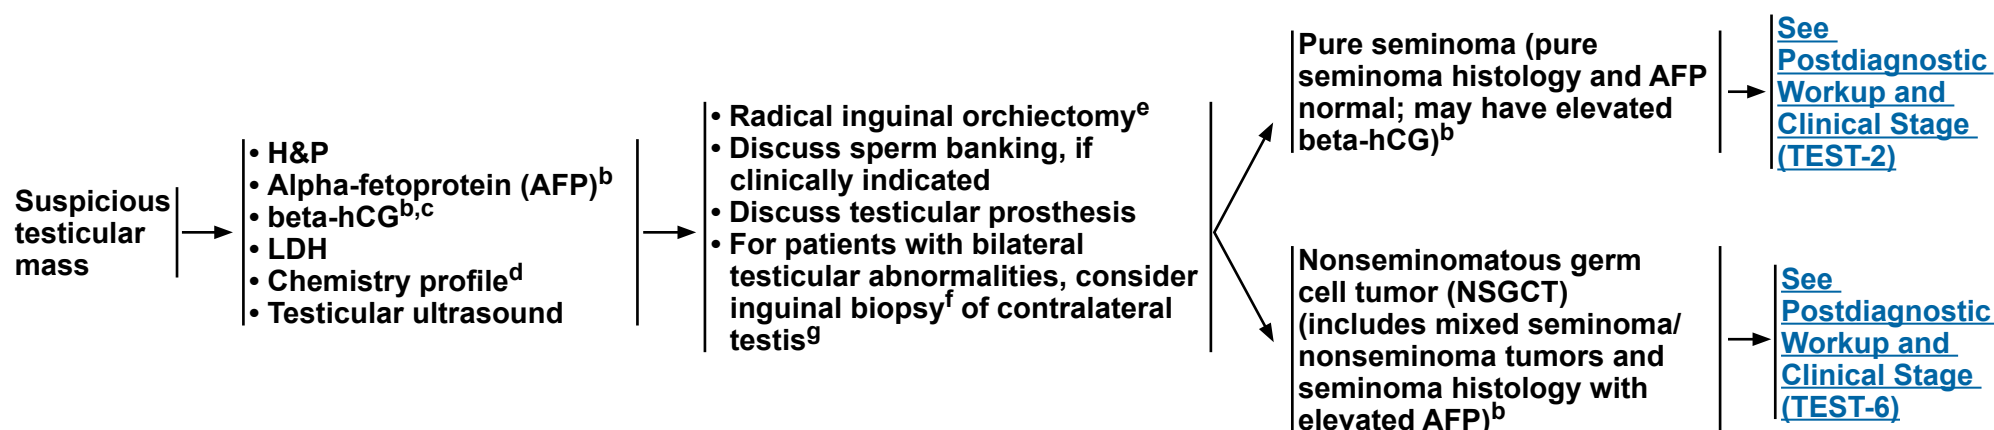

- Testis-Sparing Surgery (TSS)
- First sub-bullet, second sub-bullet modified: Non-palpable testicular masses <2 cm are associated with benign tumors in up to 80% of patients, and therefore, TSS may be considered in these patients in whom TSS is technically feasible. ~~to avoid orchiectomy in patients with benign tumors.~~

TEST-H 2 of 2

- Postchemotherapy Setting
 - ▶ Fifth bullet modified: Limited data suggest increased frequency of aberrant recurrences with the use of minimally invasive laparoscopic or robotic approaches to RPLND. Therefore, minimally invasive RPLND is not recommended as standard management ~~at this time~~, *but can be considered in highly selected cases at high-volume centers.*

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**WORKUP****PRIMARY TREATMENT^a****PATHOLOGIC DIAGNOSIS**

^a Though rare, when a patient presents with rapidly increasing beta-hCG or AFP and symptoms related to disseminated disease with a testicular mass, chemotherapy can be initiated immediately without waiting for a biopsy diagnosis or performing orchiectomy. However, orchiectomy should be performed at completion of chemotherapy.

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion](#).

^c Quantitative analysis of beta subunit.

^d Consider measuring baseline levels of gonadal function.

^e May consider testis-sparing surgery (ie, partial orchiectomy) in select patients. [See Principles of Surgery \(TEST-H\)](#).

^f Inguinal exploration with exposure of testis, with direct observation and partial orchiectomy. [See Principles of Surgery \(TEST-H\)](#).

^g If ultrasound shows cryptorchid testis, marked atrophy, or suspicious mass. Biopsies are not recommended for microcalcifications.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

PATHOLOGIC DIAGNOSIS

POSTDIAGNOSTIC WORKUP

CLINICAL STAGE

Pure seminoma^h
(pure seminoma histology
and AFP normal;ⁱ may
have elevated beta-hCG^b)

- Abdominal/pelvic CT
- Chest x-ray
- Chest CT if:
 - ▶ Positive abdominal CT or abnormal chest x-ray
- Repeat beta-hCG, LDH, and AFP since TNM staging is based on post-orchietomy values^{b,j}
- Brain MRI,^k if clinically indicated^l
- Recommend sperm banking, if clinically indicated

Stage
IA, IB^m

Stage
IS

Stage
IIA,ⁿ IIB

Stage
IIC, III^m

[See Primary Treatment
and Follow-up \(TEST-3\)](#)

[See Primary Treatment
and Follow-up \(TEST-4\)](#)

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion](#).

^h Mediastinal primary seminoma should be treated by risk status used for gonadal seminomas with etoposide/cisplatin for 4 cycles or bleomycin/etoposide/cisplatin for 3 cycles.

ⁱ If AFP is elevated, treat as nonseminoma.

^j Elevated values should be followed after orchiectomy with repeated determination to allow precise staging. Follow declining markers until normalization or nadir. Staging is based on marker levels at the time that the patient starts postorchietomy therapy (for example, for patients starting chemotherapy for disseminated disease, prognostic category and staging should be assigned based on the serum tumor marker levels on day 1 of cycle 1 of chemotherapy).

^k With and without contrast.

^l Eg, beta-hCG >5000 IU/L, non-pulmonary visceral metastases, extensive lung metastasis, or neurologic symptoms present.

^m The panel recommends staging tumors with discontinuous invasion of the spermatic cord as pT3 (high-risk stage I) and not as M1 (stage III) as is recommended in the 8th edition of the AJCC Cancer Staging Manual. If surveillance is elected, the pelvis should be included in the imaging due to a higher risk of pelvic relapses in these patients. [See Discussion](#).

ⁿ For select cases of clinical stage IIA disease with borderline retroperitoneal lymph nodes, waiting 4–6 weeks and repeating imaging (chest/abdomen/pelvic CT with contrast) to confirm staging before initiating treatment can be considered.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

CLINICAL STAGE	PRIMARY TREATMENT ^o	FOLLOW-UP
Stage IA, IB	Surveillance for pT1–pT3 tumors (strongly preferred)	See Follow-up for Seminoma, Table 1 (TEST-A 1 of 2) → Recurrence, treat according to extent of disease at relapse ^v
	or	
	Single-agent carboplatin ^{p,q} (AUC=7 x 1 cycle or AUC=7 x 2 cycles)	See Follow-up for Seminoma, Table 2 (TEST-A 1 of 2) → Recurrence, treat according to extent of disease at relapse ^v
	or	
	RT ^r (20 Gy or 25.5 Gy) ^s	See Follow-up for Seminoma, Table 2 (TEST-A 1 of 2) → Recurrence, treat according to extent of disease at relapse ^v
Stage IS		Repeat elevated serum tumor marker measurement ^b and assess with chest/abdominal/pelvic CT (with contrast) to scan for evaluable disease ^{t,u} → Recurrence, treat according to extent of disease at relapse ^v

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion](#).

^o Discuss sperm banking prior to chemotherapy or radiation treatment.

^p Recommend abdomen/pelvic CT scan and chest x-ray or CT scan within the 4 weeks prior to the initiation of chemotherapy to confirm staging, even if scan was done previously. [See Principles of Imaging \(TEST-I\)](#).

^q There are limited long-term follow-up data on the toxicity and efficacy of carboplatin. A recent population-based study suggested patients with larger tumors, rete testis involvement, or both derive a smaller reduction in relapse rate with 1 cycle of carboplatin than previously reported. [See Discussion](#).

^r [See Principles of Radiotherapy for Pure Testicular Seminoma \(TEST-C\)](#).

^s For stage I seminoma, long-term follow-up studies indicate an increase in late toxicities with radiation treatment. [See Discussion](#).

^t For further information on stage IS, [see Discussion](#).

^u Elevated tumor markers increase the risk of disease outside of the retroperitoneum. Therefore, systemic therapy should be encouraged. [See Primary Chemotherapy Regimens for Germ Cell Tumors \(TEST-E\)](#).

^v Patients should not be treated based upon an elevated LDH alone.

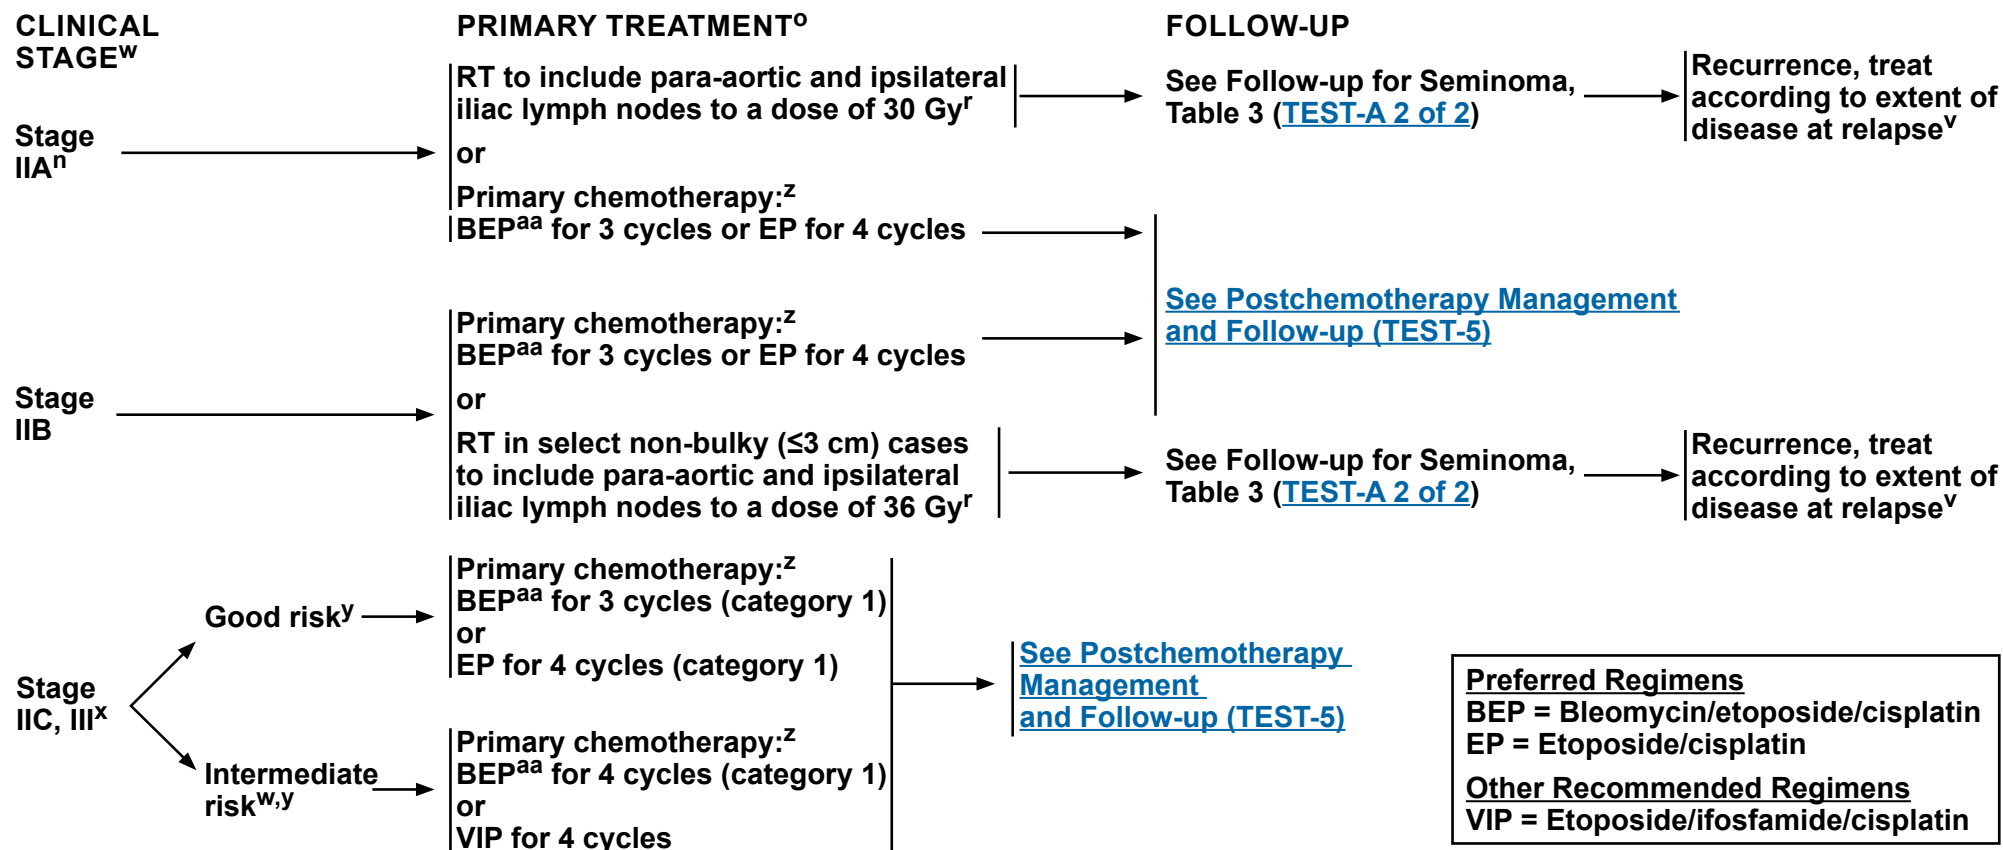

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

ⁿ For select cases of clinical stage IIA disease with borderline retroperitoneal lymph nodes, waiting 4–6 weeks and repeating imaging (chest/abdomen/pelvic CT with contrast) to confirm staging before initiating treatment can be considered.

^o Discuss sperm banking prior to chemotherapy or radiation treatment.

^r [See Principles of Radiotherapy for Pure Testicular Seminoma \(TEST-C\).](#)

^v Patients should not be treated based upon an elevated LDH alone.

^w Intermediate risk in seminoma is based on metastases to organs other than the lungs (stage IIIC). Stage IIIB does not apply to pure seminomas. Patients with elevated AFP have nonseminomas. In patients with a serum beta-hCG >1000 IU/L, consider the possibility of an NSGCT, re-review surgical specimen with pathology, and consider discussion with a high-volume center. LDH and beta-hCG alone should not be used to stage or risk stratify patients with pure seminoma.

^x All stage IIC and stage III seminomas are considered good-risk disease except for stage III disease with non-pulmonary visceral metastases (eg, bone, liver, brain), which is considered intermediate risk.

^y [See Risk Classification for Advanced Disease \(TEST-D\).](#)

^z [See Primary Chemotherapy Regimens for Germ Cell Tumors \(TEST-E\).](#)

^{aa} Consider a bleomycin-free regimen in patients with reduced or borderline glomerular filtration rate (GFR) and in patients older than 50 years of age.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

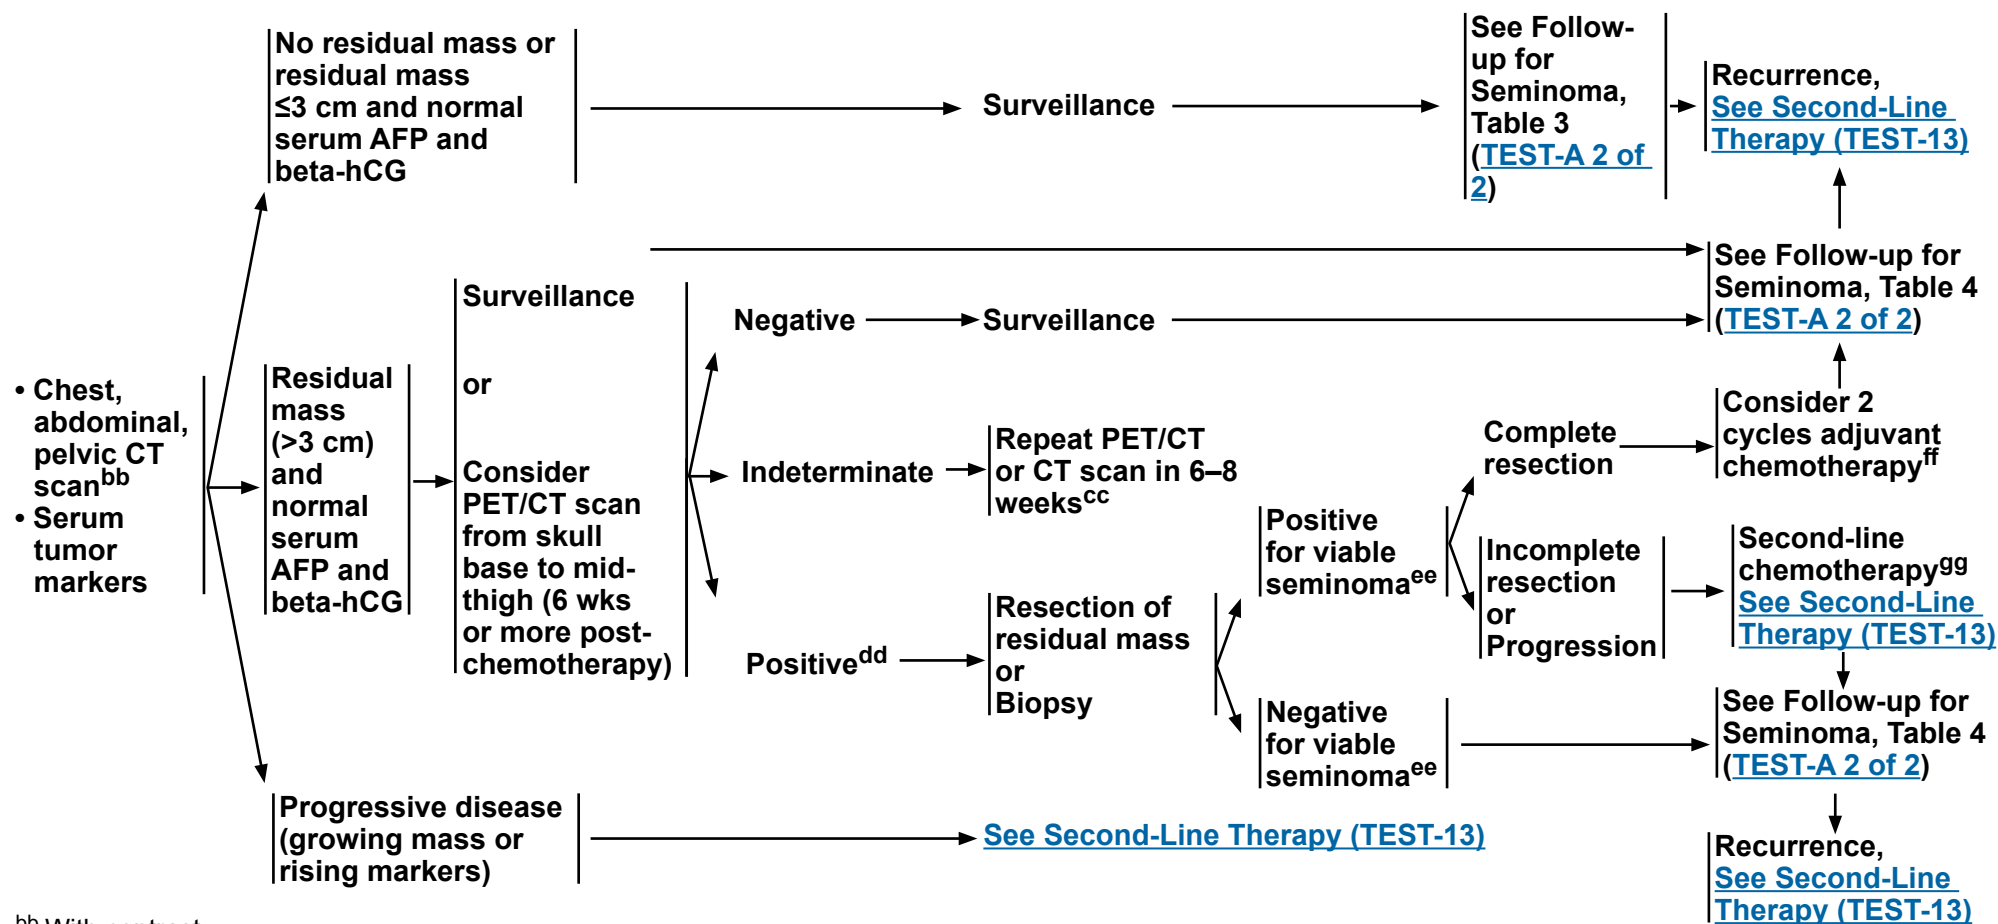

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

STAGE IIA, IIB, IIC, III AFTER PRIMARY TREATMENT WITH CHEMOTHERAPY

POSTCHEMOTHERAPY MANAGEMENT

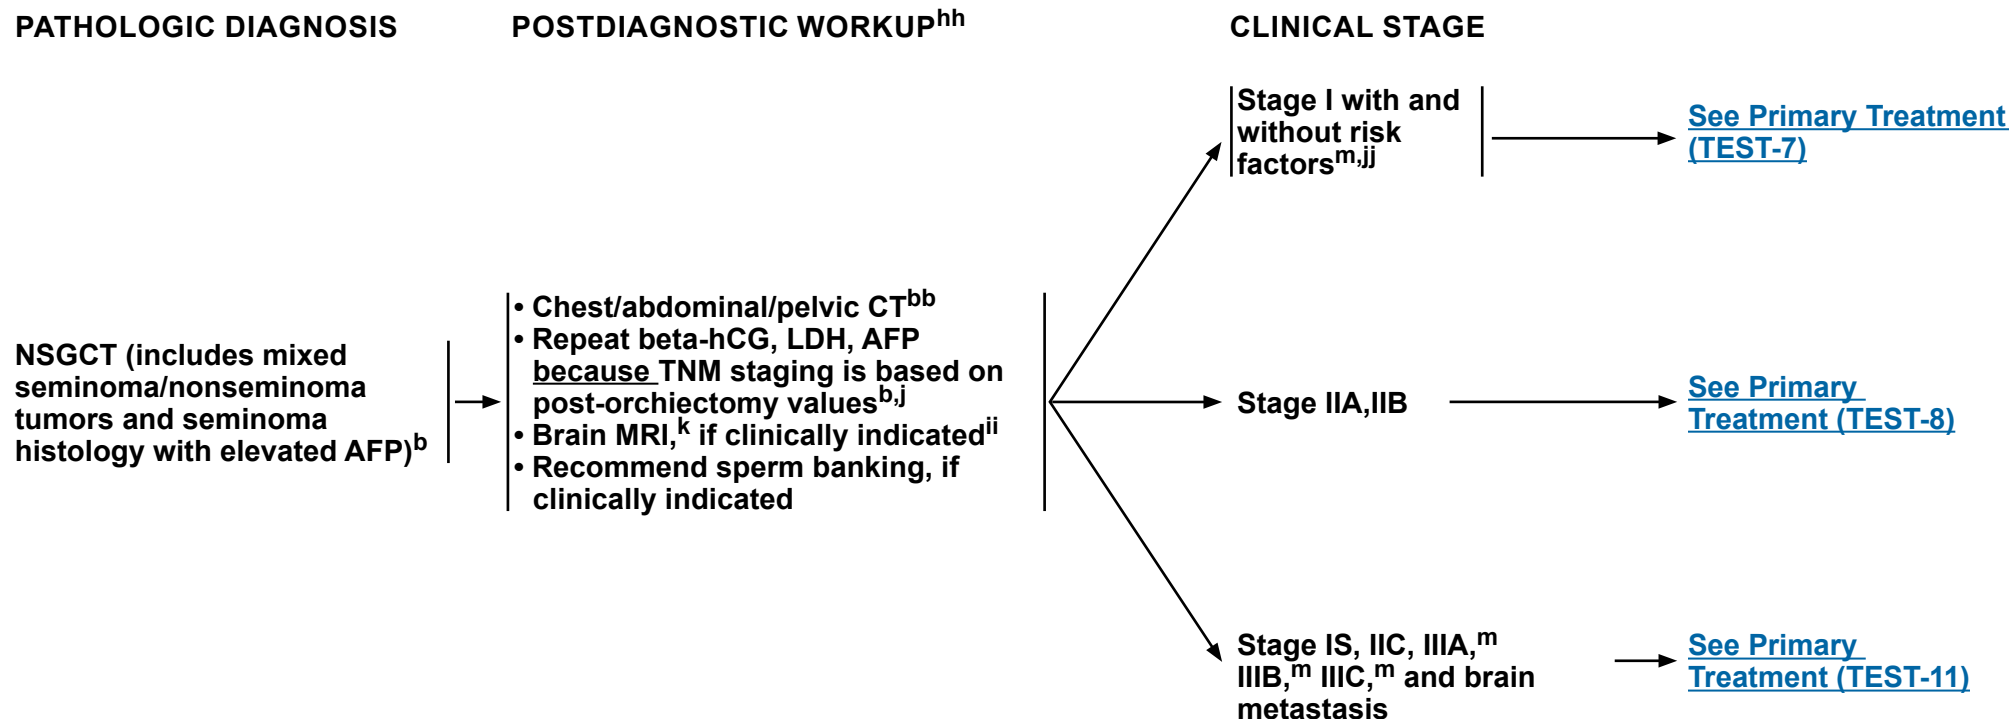

FOLLOW-UP

^{bb} With contrast.^{cc} If still indeterminate, recommend following with CT scan or biopsy.^{dd} [See Principles of Imaging \(TEST-1\)](#).^{ee} In rare cases, nonseminomatous elements will be identified. If they are non-teratomatous, then proceed in the same fashion as for viable seminoma above.^{ff} If complete resection of all residual disease, consider chemotherapy for 2 cycles (EP or TIP or VIP or VeIP). If resection incomplete, full course of second-line therapy is recommended ([see TEST-13](#)). If a biopsy is performed and is positive, consider surgery if complete resection is possible or full course of second-line chemotherapy.^{gg} [See Second-Line Chemotherapy Regimens for Metastatic Germ Cell Tumors \(TEST-F\)](#).**Note:** All recommendations are category 2A unless otherwise indicated.**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion](#).

^j Elevated values should be followed after orchietomy with repeated determination to allow precise staging. Follow declining markers until normalization or nadir. Staging is based on marker levels at the time that the patient starts postorchietomy therapy (for example, for patients starting chemotherapy for disseminated disease, prognostic category and staging should be assigned based on the serum tumor marker levels on day 1 of cycle 1 of chemotherapy).

^k With and without contrast.

^m The panel recommends staging tumors with discontinuous invasion of the spermatic cord as pT3 (high-risk stage I) and not as M1 (stage III) as is recommended in the 8th edition of the AJCC Cancer Staging Manual. If surveillance is elected, the pelvis should be included in the imaging due to a higher risk of pelvic relapses in these patients. [See Discussion](#).

^{bb} With contrast.

^{hh} PET/CT scan is not clinically indicated for nonseminoma.

ⁱⁱ Eg, beta-hCG >5000 IU/L, extensive lung metastasis, choriocarcinoma, neurologic symptoms, non-pulmonary visceral metastasis, or AFP >10,000 ng/mL.

^{jj} Risk factors for recurrence include lymphovascular invasion or invasion of spermatic cord or scrotum. Some centers consider predominance of embryonal carcinoma as an additional risk factor for relapse.

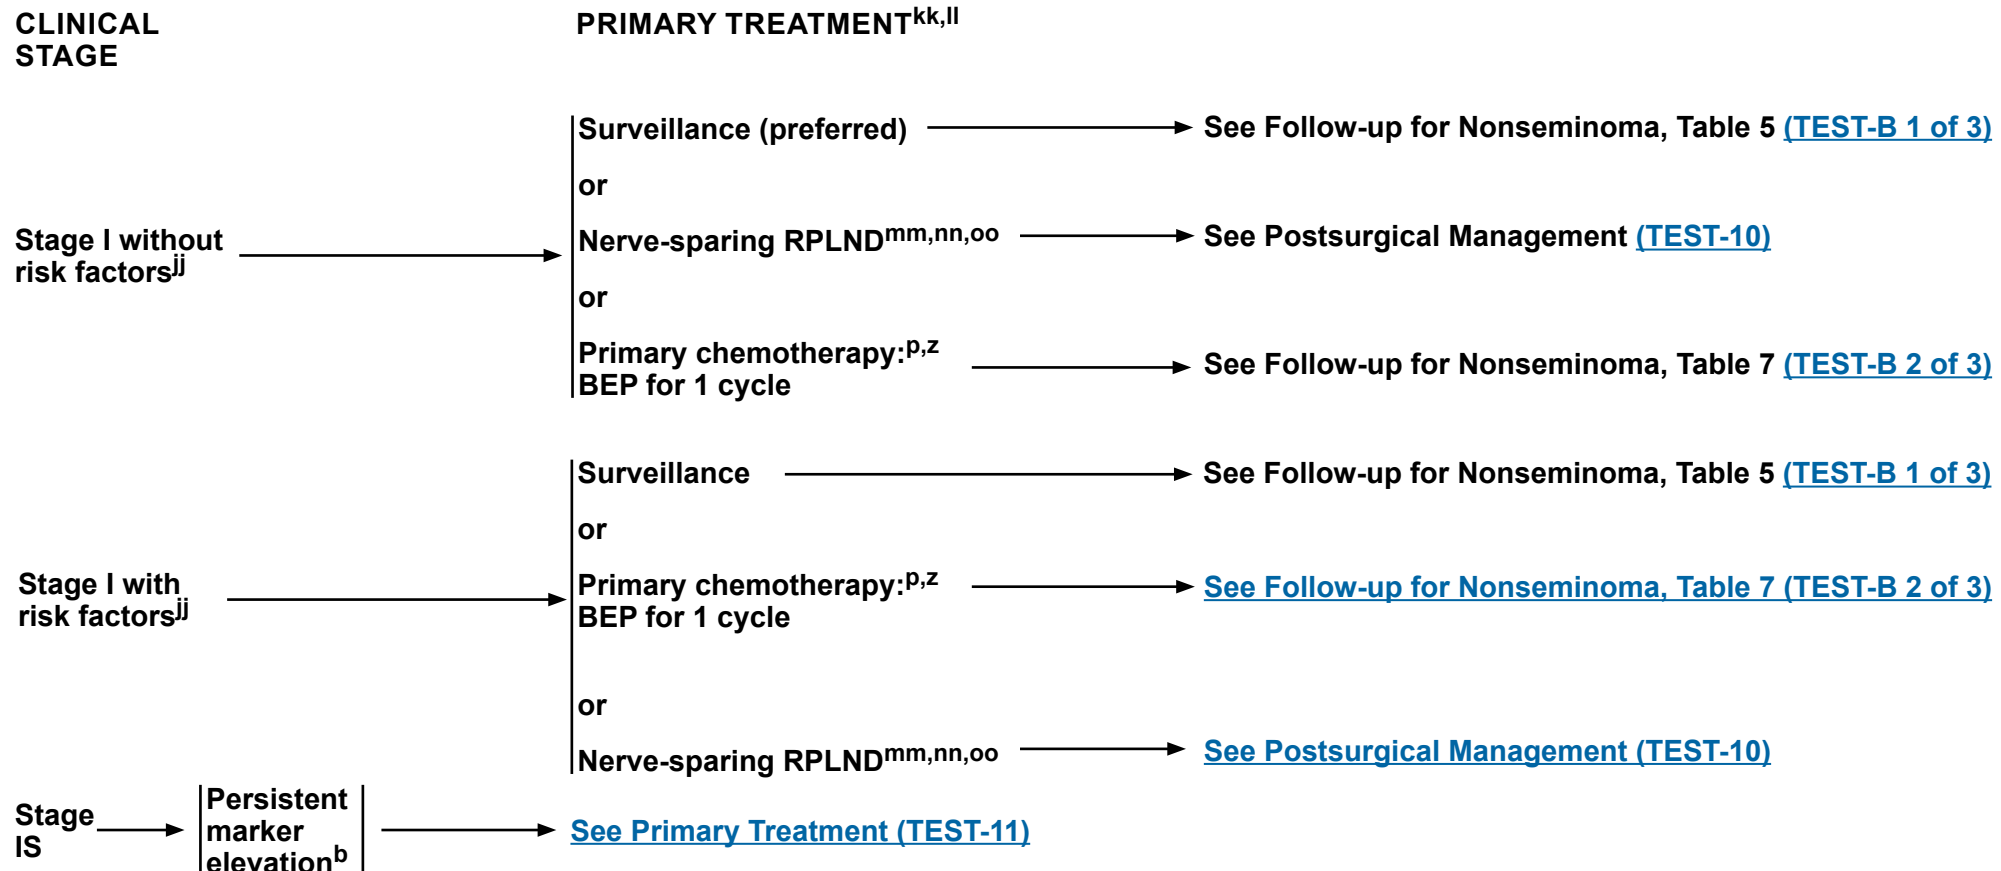

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion](#).

^p Recommend abdomen/pelvic CT scan and chest x-ray or CT scan within the 4 weeks prior to the initiation of chemotherapy to confirm staging, even if scan was done previously. [See Principles of Imaging \(TEST-I\)](#).

^z [See Primary Chemotherapy Regimens for Germ Cell Tumors \(TEST-E\)](#).

^{jj} Risk factors for recurrence include lymphovascular invasion or invasion of spermatic cord or scrotum. Some centers consider predominance of embryonal carcinoma as an additional risk factor for relapse.

^{kk} Treatment options listed based on preference. [See Discussion](#).

^{ll} Retroperitoneal lymph node dissection (RPLND) is preferred as primary treatment for tumors with transformed teratoma. Patients with stage I pure teratoma and normal markers should receive either surveillance or RPLND. [See Discussion](#).

^{mm} RPLND is recommended within 4 weeks of CT scan and 7–10 days of marker measurement.

ⁿⁿ [See Principles of Surgery for Germ Cell Tumors \(TEST-H\)](#).

^{oo} Recommend referral to a high-volume center.

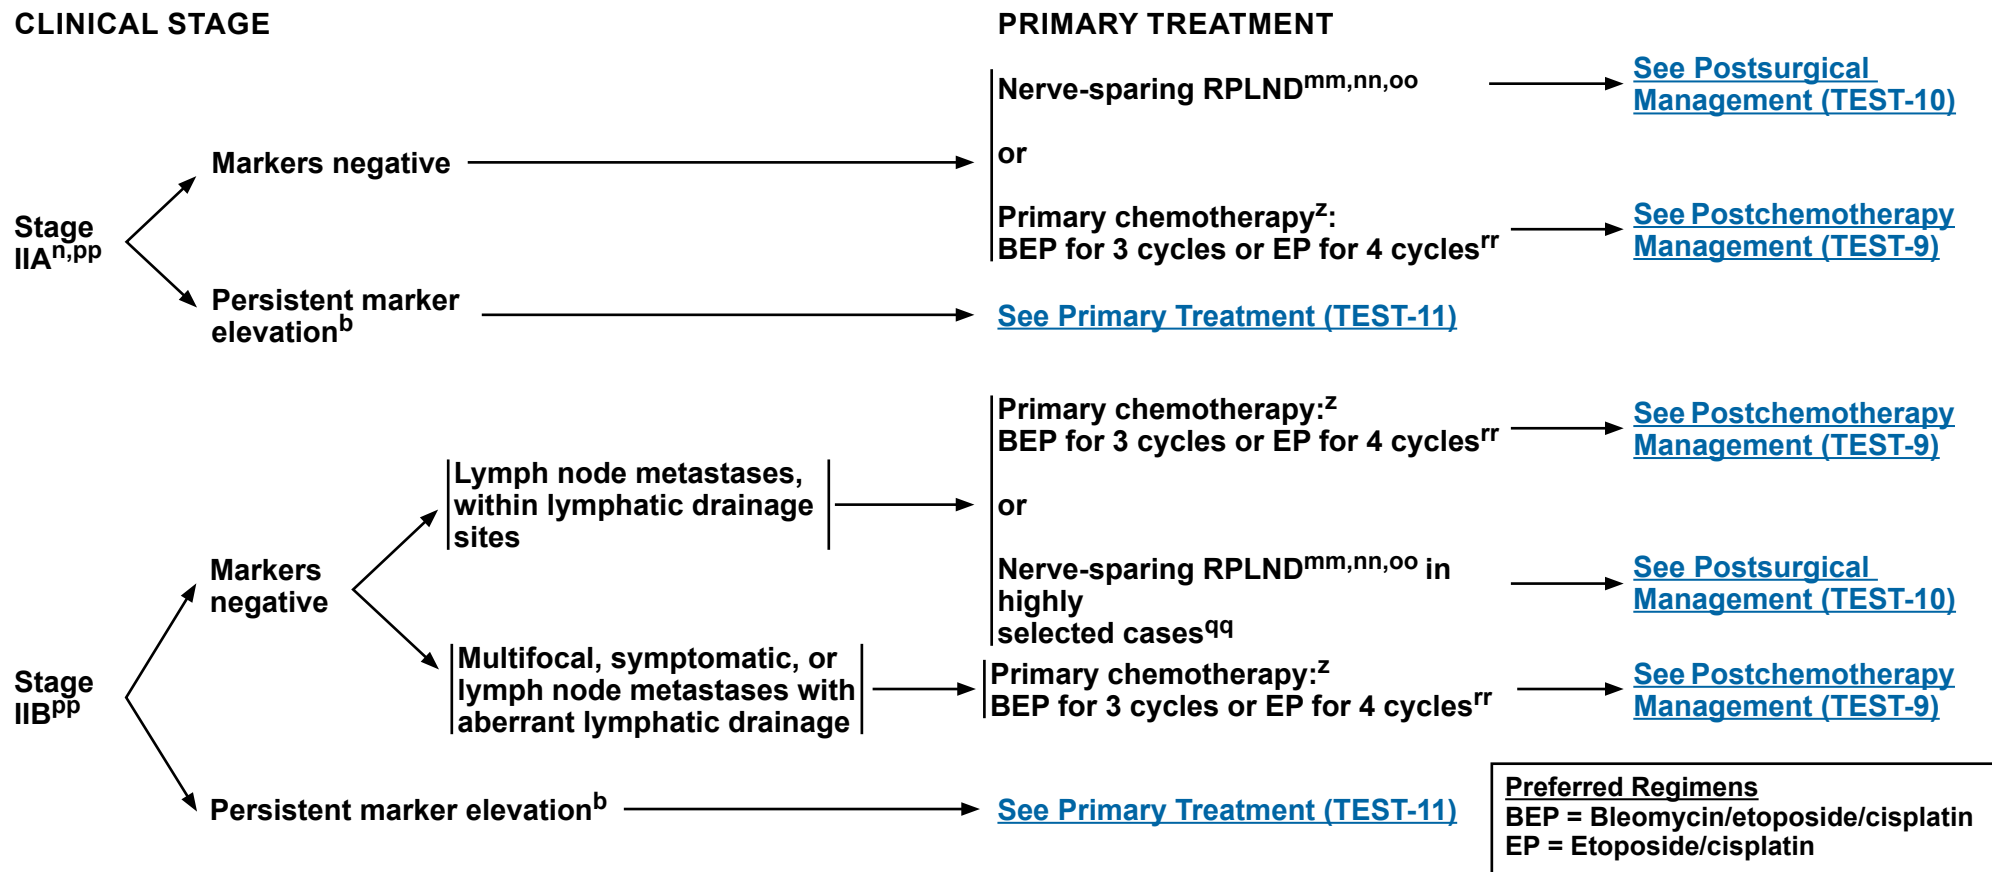

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion.](#)

ⁿ For select cases of clinical stage IIA disease with borderline retroperitoneal lymph nodes, waiting 4–6 weeks and repeating imaging (chest/abdomen/pelvic CT with contrast) to confirm staging before initiating treatment can be considered.

^z [See Primary Chemotherapy Regimens for Germ Cell Tumors \(TEST-E\).](#)

^{mm} RPLND is recommended within 4 weeks of CT scan and 7–10 days of marker measurement.

ⁿⁿ [See Principles of Surgery for Germ Cell Tumors \(TEST-H\).](#)

^{oo} Recommend referral to a high-volume center.

^{pp} RPLND is preferred as primary treatment for stage II tumors with somatic type malignancy (previously referred to as transformed teratoma) [See Discussion.](#)

^{qq} RPLND should be considered for stage II tumors with teratoma predominance in patients with normal markers.

^{rr} Patients who are at higher risk for bleomycin-related complications. Bleomycin-based regimens should not be given to patients >50 years of age, those at increased risk for pulmonary complications, those with underlying lung disease, etc.

Note: All recommendations are category 2A unless otherwise indicated.

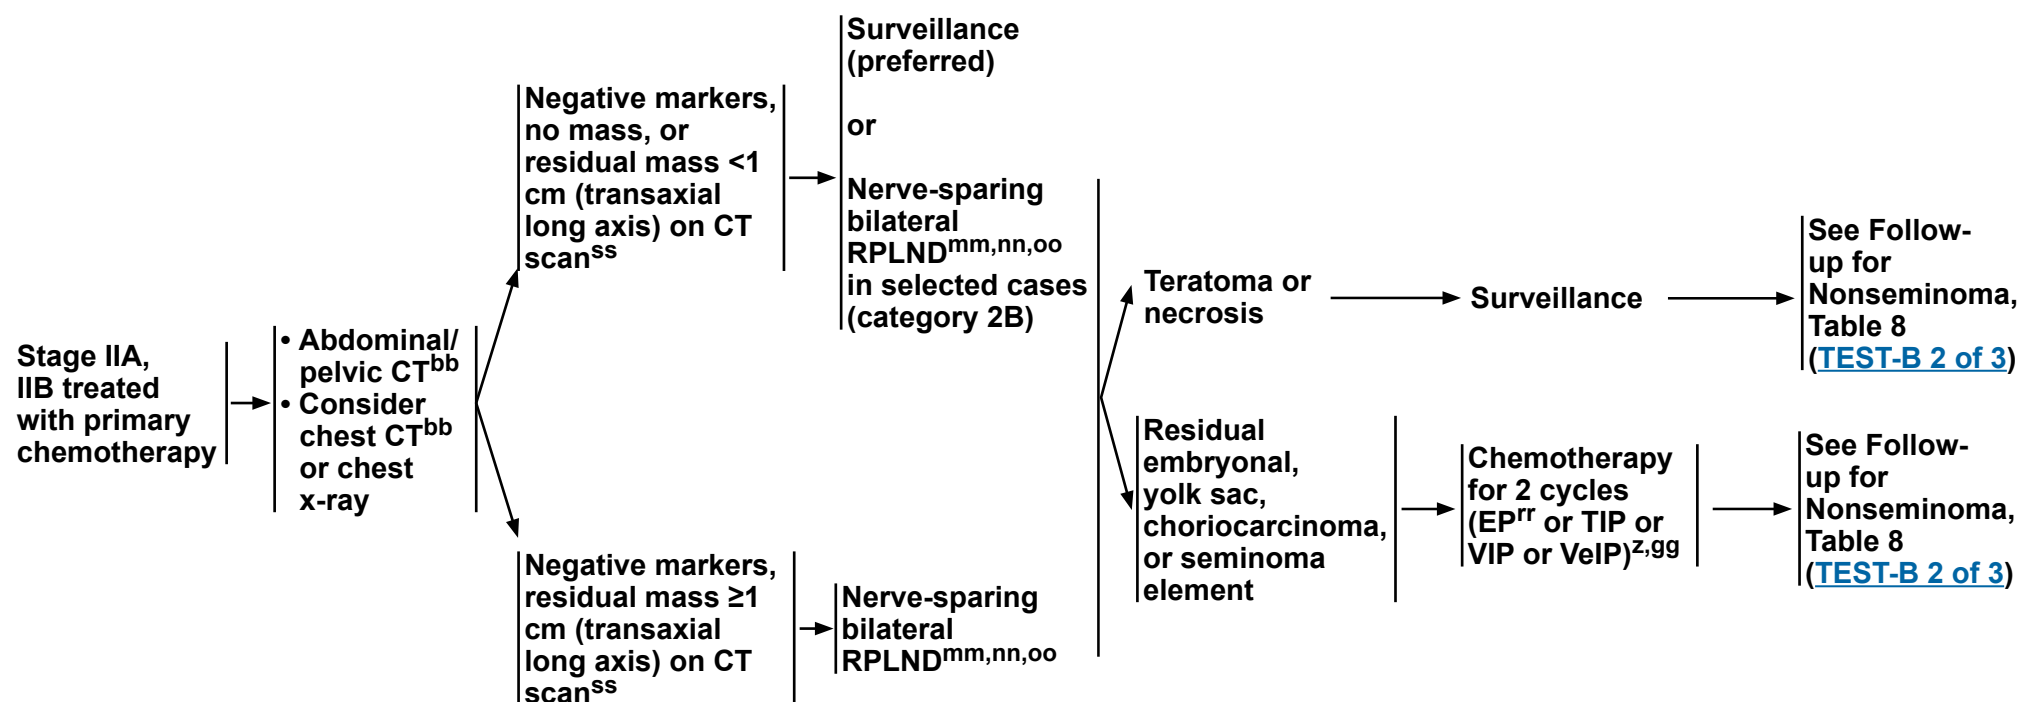

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

POSTCHEMOTHERAPY MANAGEMENT

^z See [Primary Chemotherapy Regimens for Germ Cell Tumors \(TEST-E\)](#).

^{bb} With contrast.

^{gg} See [Second-Line Chemotherapy Regimens for Metastatic Germ Cell Tumors \(TEST-F\)](#).

^{mm} RPLND is recommended within 4 weeks of CT scan and 7–10 days of marker measurement.

ⁿⁿ See [Principles of Surgery for Germ Cell Tumors \(TEST-H\)](#).

^{oo} Recommend referral to a high-volume center.

^{rr} Patients who are at higher risk for bleomycin-related complications. Bleomycin-based regimens should not be given to patients >50 years of age, those at increased risk for pulmonary complications, those with underlying lung disease, etc.

^{ss} Craniocaudal axis should not be used.

Note: All recommendations are category 2A unless otherwise indicated.

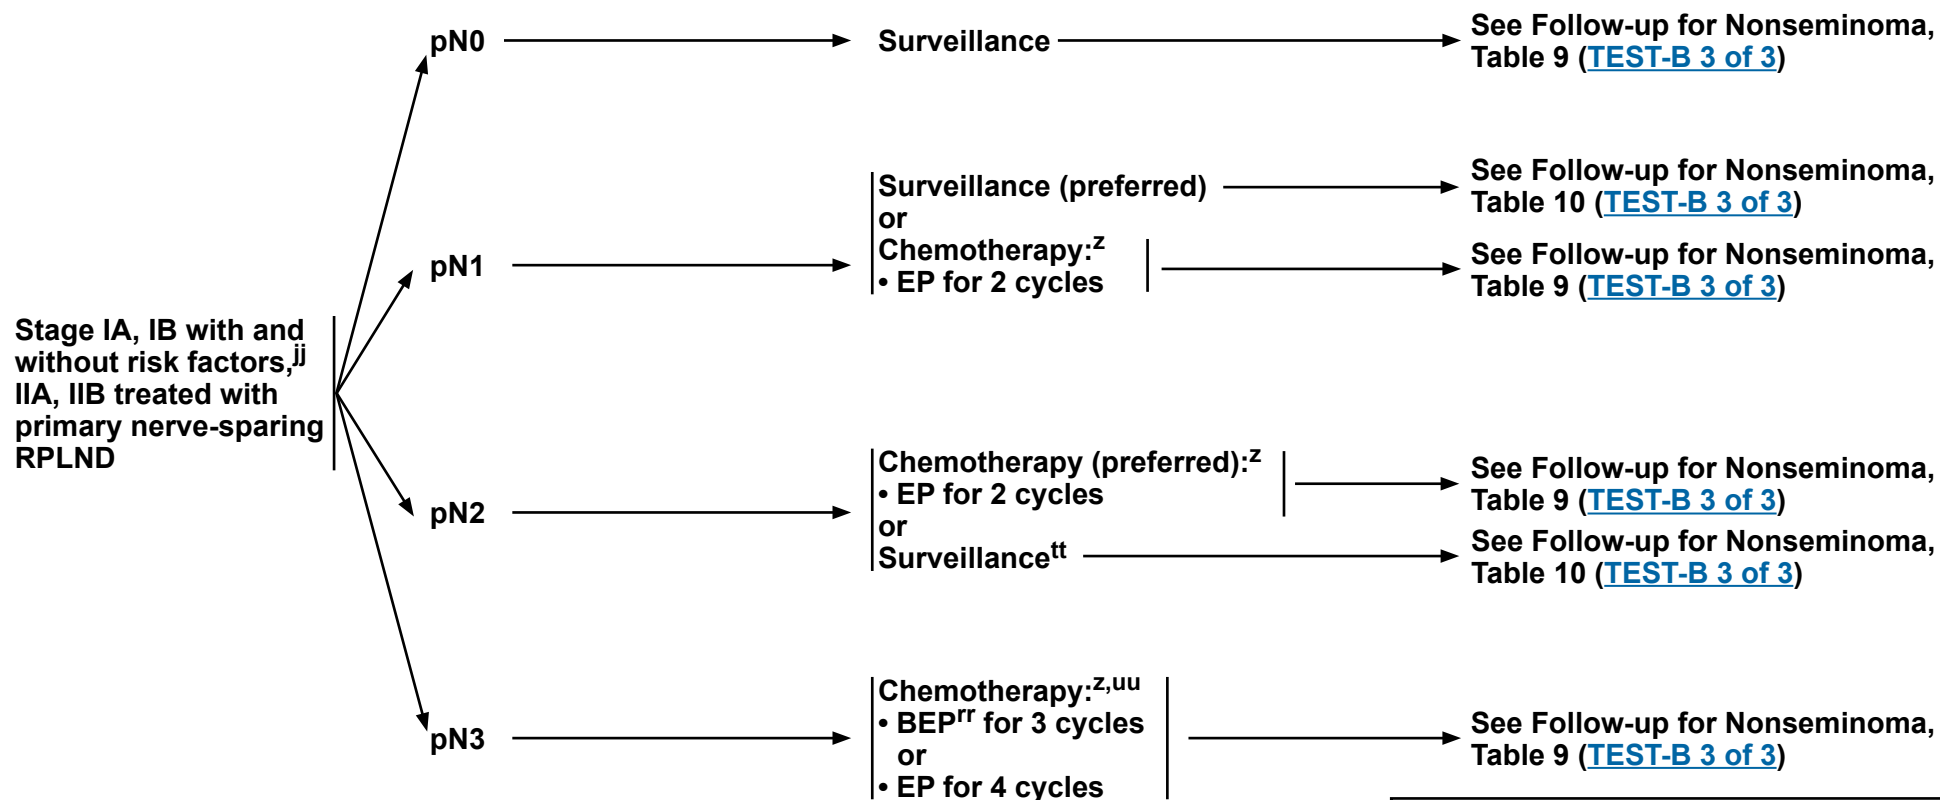

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

POSTSURGICAL MANAGEMENT

^z See [Primary Chemotherapy Regimens for Germ Cell Tumors \(TEST-E\)](#).

^{jj} Risk factors for recurrence include lymphovascular invasion or invasion of spermatic cord or scrotum. Some centers consider predominance of embryonal carcinoma as an additional risk factor for relapse.

^{rr} Patients who are at higher risk for bleomycin-related complications. Bleomycin-based regimens should not be given to patients >50 years of age, those at increased risk for pulmonary complications, those with underlying lung disease, etc.

^{tt} Surveillance is preferred for patients who have pure teratoma.

^{uu} This is a rare circumstance. BEP for 2 cycles is an option.

<p>pN1, pN2 Preferred Regimens EP = Etoposide/cisplatin</p>
<p>pN3 Preferred Regimens BEP = Bleomycin/etoposide/cisplatin EP = Etoposide/cisplatin</p>

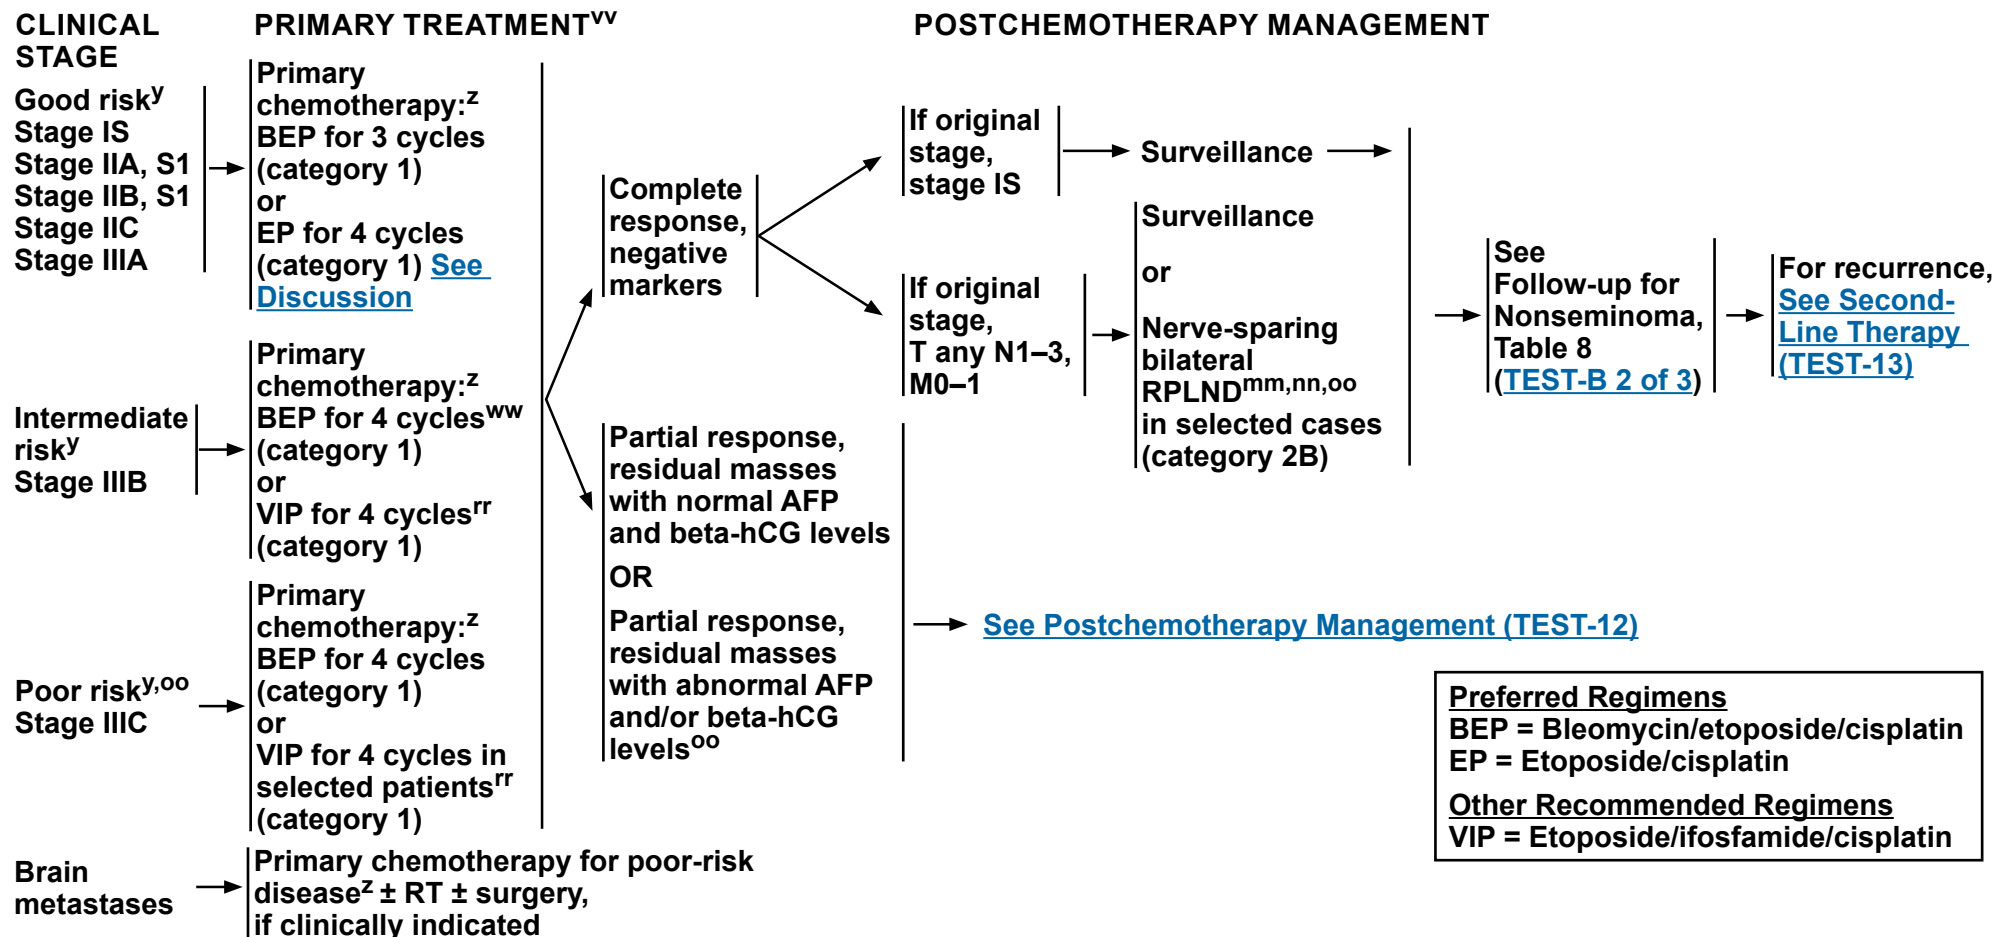

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

^y See Risk Classification for Advanced Disease (TEST-D).

^z See Primary Chemotherapy Regimens for Germ Cell Tumors (TEST-E).

^{mm} RPLND is recommended within 4 weeks of CT scan and 7–10 days of marker measurement.

ⁿⁿ See Principles of Surgery for Germ Cell Tumors (TEST-H).

^{oo} Recommend referral to a high-volume center.

^{rr} Patients who are at higher risk for bleomycin-related complications. Bleomycin-based regimens should not be given to patients >50 years of age, those at increased risk for pulmonary complications, those with underlying lung disease, etc.

^{vv} To assess response after treatment, CT with contrast of chest/abdomen/pelvis and any other sites of disease is recommended. PET has no role in assessing treatment response and residual masses following chemotherapy in patients with nonseminoma.

^{ww} If intermediate risk is based only on LDH 1.5–3 times the upper limit of normal (ULN), then BEP for 3 cycles or EP x 4 cycles can be considered.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

RESPONSE AFTER PRIMARY TREATMENT

Partial response,
residual masses
with normal AFP
and beta-hCG levels

Surgical

Follow-up for
Nonseminoma,
Table 8
([TEST-B 2 of 3](#))

For
recurrence,
[See Second-
Line Therapy
\(TEST-13\)](#)

Preferred Regimens

EP^{zz} = Etoposide/cisplatin

TIP = Paclitaxel/ifosfamide/cisplatin

VIP = Etoposide/ifosfamide/cisplatin

VeIP = Vinblastine/ifosfamide/cisplatin

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion](#).

^z [See Primary Chemotherapy Regimens for Germ Cell Tumors \(TEST-E\)](#).

^{gg} [See Second-Line Chemotherapy Regimens for Metastatic Germ Cell Tumors \(TEST-F\)](#).

^{oo} Recommend referral to a high-volume center.

^{xx} Consider brain imaging and testicular ultrasound in patients with elevated or rising markers after primary or secondary chemotherapy to evaluate for occult brain metastases or contralateral primary disease.

^{yy} If there is a teratoma with somatic-type malignancy, consider histology-directed therapy and referral to an academic center with a high-volume germ cell tumor unit.

^{zz} Consider EP for low-volume residual disease.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

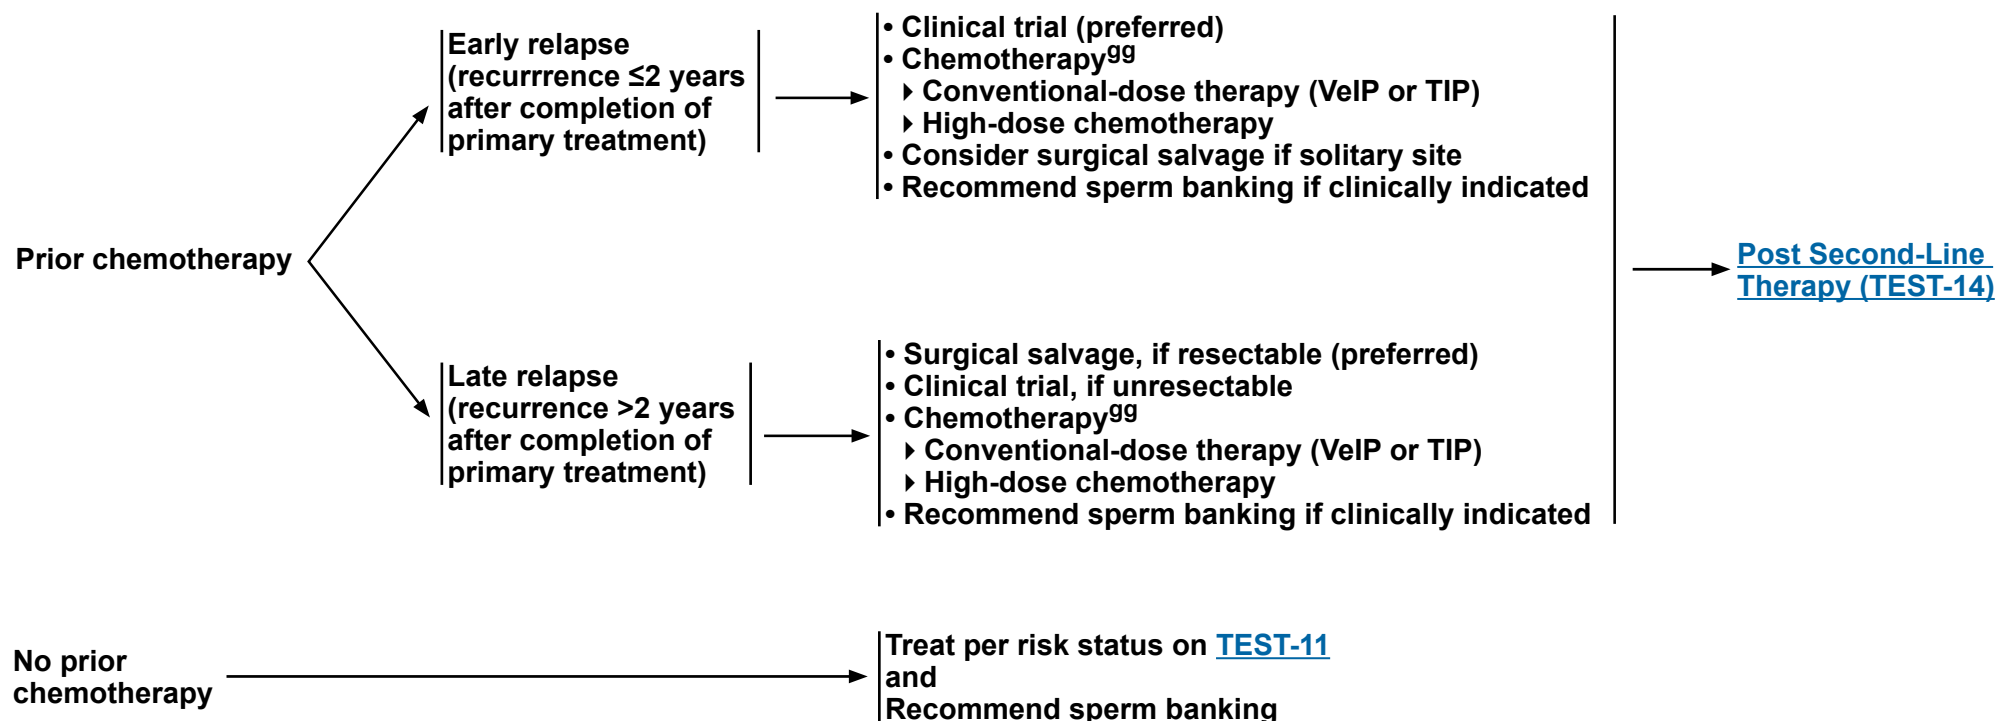

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

RECURRENCE^{aaa}

SECOND-LINE THERAPY^{vv,bbb}

Preferred Regimens

- High-dose chemotherapy^{gg}
- TIP = Paclitaxel/ifosfamide/cisplatin
- VeIP = Vinblastine/ifosfamide/cisplatin

^{gg} See [Second-Line Chemotherapy Regimens for Metastatic Germ Cell Tumors \(TEST-F\)](#).

^{vv} To assess response after treatment, CT with contrast of chest/abdomen/pelvis and any other sites of disease is recommended. PET has no role in assessing treatment response and residual masses following chemotherapy in patients with nonseminoma.

^{aaa} It is preferred that patients with recurrent nonseminoma be treated at centers with expertise in the management of this disease.

^{bbb} Includes best supportive care and palliative care. See [NCCN Guidelines for Palliative Care](#).

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

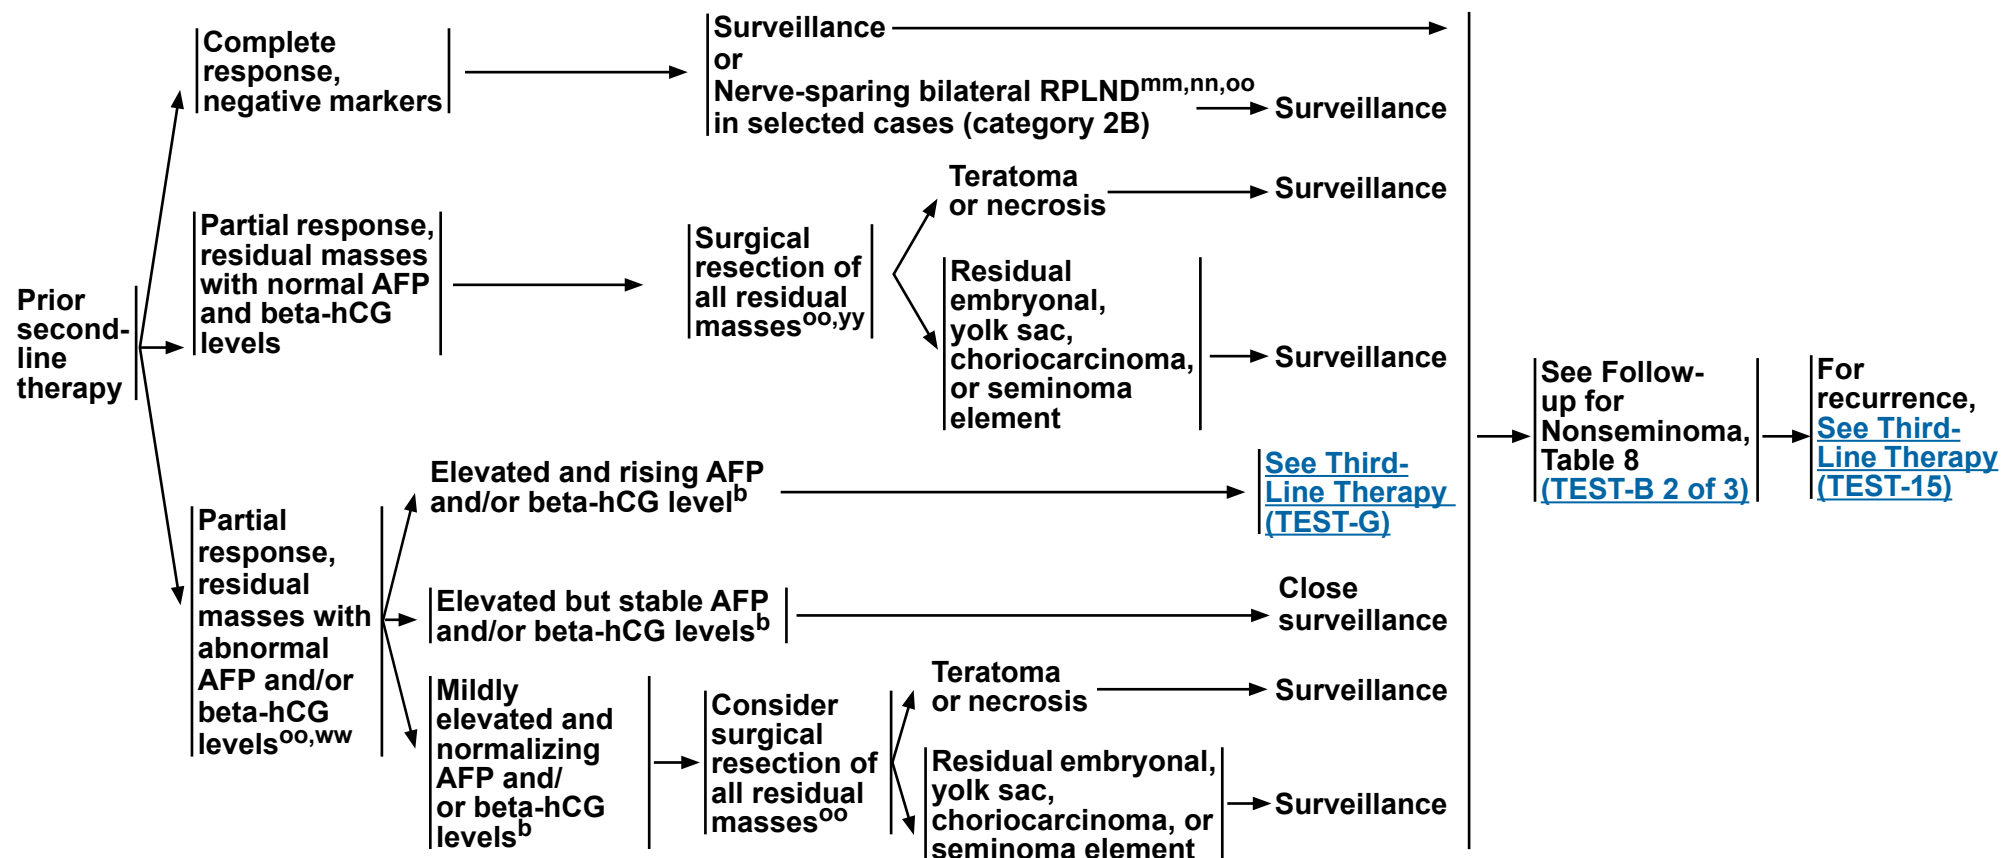

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

RECURRENCE^{aaa}

POST SECOND-LINE THERAPY^{vv,bbb}

^b Mildly elevated, non-rising AFP levels may not indicate presence of germ cell tumor. Decisions to treat should not be based on AFP values <20 ng/mL. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L) since other factors, including hypogonadism and marijuana use, can cause false-positive results. [See Discussion](#).

^{mm} RPLND is recommended within 4 weeks of CT scan and 7–10 days of marker measurement.

ⁿⁿ [See Principles of Surgery for Germ Cell Tumors \(TEST-H\)](#).

^{oo} Recommend referral to a high-volume center.

^{vv} To assess response after treatment, CT with contrast of chest/abdomen/pelvis and any other sites of disease is recommended. PET has no role in assessing treatment response and residual masses following chemotherapy in patients with nonseminoma.

^{ww} If intermediate risk is based only on LDH 1.5–3 times the upper limit of normal (ULN), then BEP for 3 cycles or EP x 4 cycles can be considered.

^{yy} If there is a teratoma with somatic-type malignancy, consider histology-directed therapy and referral to an academic center with a high-volume germ cell tumor unit.

^{aaa} It is preferred that patients with recurrent nonseminoma be treated at centers with expertise in the management of this disease.

^{bbb} Includes best supportive care and palliative care. [See NCCN Guidelines for Palliative Care](#).

Note: All recommendations are category 2A unless otherwise indicated.

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

FOLLOW-UP FOR SEMINOMA

No single follow-up plan is appropriate for all patients. The follow-up for seminoma tables is to provide guidance, and should be modified for the individual patient based on sites of disease, biology of disease, and length of time on treatment *and may be extended beyond 5 years at the discretion of the physician*. Reassessment of disease activity should be performed in patients with new or worsening signs or symptoms of disease, regardless of the time interval from previous studies. Further study is required to define optimal follow-up duration. [See NCCN Guidelines for Survivorship](#).

Table 1 Clinical Stage I Seminoma: Surveillance After Orchiectomy

	Year (at month intervals)				
	1	2	3	4	5 ^d
H&P ^{a,b}	Every 3–6 mo	Every 6 mo	Every 6–12 mo	Annually	Annually
Abdominal ± Pelvic CT ^{c,e}	At 4–6, and 12 mo	Every 6 mo	Every 6–12 mo	Every 12–24 mo	
Chest x-ray	As clinically indicated, consider chest CT with contrast in symptomatic patients.				

If Recurrence, treat according to extent of disease at relapse

Table 2 Clinical Stage I Seminoma: Surveillance After Adjuvant Treatment (Chemotherapy or Radiation)

	Year (at month intervals)				
	1	2	3	4	5 ^d
H&P ^{a,b}	Every 6–12 mo	Every 6–12 mo	Annually	Annually	Annually
Abdominal ± Pelvic CT ^{c,e}	Annually	Annually	Annually	—	
Chest x-ray	As clinically indicated, consider chest CT with contrast in symptomatic patients.				

If Recurrence, treat according to extent of disease at relapse

^a Serum tumor markers are optional.

^b Testicular ultrasound for any equivocal exam.

^c With or without contrast.

^d CT is not recommended beyond 5 years unless clinically indicated.

^e An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include all the nodes that need to be assessed. [See Principles of Imaging \(TEST-I\)](#).

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

FOLLOW-UP FOR SEMINOMA

Table 3 Clinical Stage IIA and Non-Bulky IIB Seminoma: Surveillance After Radiotherapy or Postchemotherapy^f

	Year (at month intervals)				
	1	2	3	4	5 ^d
H&P ^{a,b}	Every 3 mo	Every 6 mo	Every 6 mo	Every 6 mo	Every 6 mo
Abdominal ± Pelvic CT ^{e,g}	At 3 mo, then at 9 or 12 mo	Annually	Annually	As clinically indicated	
Chest x-ray ^h	Every 6 mo	Every 6 mo	—		

If Recurrence, treat according to extent of disease at relapse

Table 4 Bulky Clinical Stage IIB, IIC, and Stage III Seminoma: Surveillance Postchemotherapy

	Year (at month intervals)				
	1	2	3	4	5 ^d
H&P and markers ^b	Every 2 mo	Every 3 mo	Every 6 mo	Every 6 mo	Annually
Abdominal/ Pelvic CT ^{e,g,h,i,j,k}	Every 4 mo	Every 6 mo	Annually	Annually	As clinically indicated
Chest x-ray ^h	Every 2 mo ^l	Every 3 mo ^l	Annually	Annually	Annually

If Recurrence, [see TEST-13](#).

^a Serum tumor markers are optional.

^b Testicular ultrasound for any equivocal exam.

^d CT is not recommended beyond 5 years unless clinically indicated.

^e An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include all the nodes that need to be assessed. [See Principles of Imaging \(TEST-1\)](#).

^f Assuming no residual mass or residual mass <3 cm and normal tumor markers.

^g With contrast.

^h Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in the presence of thoracic symptoms.

ⁱ Patients with PET-negative residual mass measuring >3 cm following chemotherapy should undergo an abdominal/pelvic CT scan with contrast every 6 months for the first year then annually for 5 years.

^j Patients with residual masses may require more frequent imaging based on clinical judgment.

^k PET/CT scan of skull base to mid-thigh as clinically indicated.

^l Add chest CT with contrast if supradiaphragmatic disease present at diagnosis.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

FOLLOW-UP FOR NONSEMINOMA

No single follow-up plan is appropriate for all patients. The follow-up for nonseminoma tables is to provide guidance, and should be modified for the individual patient based on sites of disease, biology of disease, and length of time on treatment *and may be extended beyond 5 years at the discretion of the physician*. Reassessment of disease activity should be performed in patients with new or worsening signs or symptoms of disease, regardless of the time interval from previous studies. Further study is required to define optimal follow-up duration.

Table 5 Clinical Stage I without Risk Factors,^a NSGCT: Active Surveillance

	Year (at month intervals)				
	1	2	3	4	5
H&P and markers ^b	Every 2 mo	Every 3 mo	Every 4–6 mo	Every 6 mo	Annually
Abdominal ± Pelvic CT ^{c,d}	Every 4–6 mo	Every 6 mo	Annually	As clinically indicated	
Chest x-ray ^e	At mo 4 and 12	Annually	Annually	Annually	As clinically indicated

If Recurrence, see [TEST-13](#).

	Year (at month intervals)				
	1	2	3	4	5
H&P and markers ^b	Every 2 mo	Every 3 mo	Every 4–6 mo	Every 6 mo	Annually
Abdominal ± Pelvic CT ^{c,d}	Every 4 mo	Every 4–6 mo	Every 6 mo	Annually	As clinically indicated
Chest x-ray ^e	Every 4 mo	Every 4–6 mo	Every 6 mo	Annually	As clinically indicated

If Recurrence, see [TEST-13](#).

^a Risk factors for recurrence include lymphovascular invasion or invasion of spermatic cord or scrotum. Some centers consider predominance of embryonal carcinoma as an additional risk factor for relapse.

^b Testicular ultrasound for any equivocal exam.

^c With contrast.

^d An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include all the nodes that need to be assessed. [See Principles of Imaging \(TEST-1\)](#).

^e Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in the presence of thoracic symptoms.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

FOLLOW-UP FOR NONSEMINOMA

Table 7 Clinical Stage IA/B NSGCT: Treated with 1 Cycle of Adjuvant BEP Chemotherapy or Primary RPLND

	Year (at month intervals)				
	1	2	3	4	5
H&P and markers ^b	Every 3 mo	Every 3 mo	Every 6 mo	Every 6 mo	Annually
Abdominal ± Pelvic CT ^{c,d}	Annually	Annually ^f	—	—	—
Chest x-ray ^e	Every 6–12 mo	Annually	—	—	—

If Recurrence, see [TEST-13](#).

Table 8 Clinical Stage II–III NSGCT: Surveillance After Complete Response to Chemotherapy ± Postchemotherapy RPLND^g

	Year (at month intervals)				
	1	2	3	4	5
H&P and markers ^b	Every 2 mo	Every 3 mo	Every 6 mo	Every 6 mo	Every 6 mo ^l
Abdominal ± Pelvic CT ^{c,d,h}	Every 6 mo	Every 6–12 mo	Annually	As clinically indicated ^k	
Chest x-ray ^{e,i}	Every 6 mo	Every 6 mo	Annually ^j	Annually ^j	—

If Recurrence, see [TEST-13](#).

^b Testicular ultrasound for any equivocal exam.

^c With contrast.

^d An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include all the nodes that need to be assessed. [See Principles of Imaging \(TEST-1\)](#).

^e Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in the presence of thoracic symptoms.

^f Optional for patients treated with primary RPLND.

^g Patients who have an incomplete response to chemotherapy require more frequent imaging than is listed on this table.

^h Patients with clinical stage II disease treated with chemotherapy who undergo postchemotherapy RPLND and are found to have pN0 disease or pN1 pure teratoma need only 1 CT scan at postoperative month 3–4 and then as clinically indicated. [See Discussion](#).

ⁱ Chest CT with contrast if supradiaphragmatic disease at baseline.

^j Chest x-ray is optional at months 36 and 48.

^k For patients with unresected residual masses or resected residual masses containing viable cancer.

^l Consider annual tumor markers for years 5–10.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer - Nonseminoma

FOLLOW-UP FOR NONSEMINOMA

Table 9 Pathologic Stage IIA/B NSGCT: Post-Primary RPLND and Treated with Adjuvant Chemotherapy

	Year (at month intervals)				
	1	2	3	4	5
H&P and markers ^b	Every 6 mo	Every 6 mo	Annually	Annually	Annually
Abdominal/ Pelvic CT ^{c,d,m}	4 mo after RPLND	As clinically indicated			
Chest x-ray ^e	Every 6 mo	Annually	Annually	Annually	Annually

If Recurrence, see [TEST-13](#).

Table 10 Pathologic Stage IIA/B NSGCT: Post-Primary RPLND and NOT Treated with Adjuvant Chemotherapyⁿ

	Year (at month intervals)				
	1	2	3	4	5
H&P and markers ^b	Every 2 mo	Every 3 mo	Every 4 mo	Every 6 mo	Annually
Abdominal/ Pelvic CT ^{c,d}	At 3–4 mo ^o	Annually	As clinically indicated		
Chest x-ray ^e	Every 2–4 mo	Every 3–6 mo	Annually	Annually	Annually

If Recurrence, see [TEST-13](#).

^b Testicular ultrasound for any equivocal exam.

^c With contrast.

^d An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include all the nodes that need to be assessed. [See Principles of Imaging \(TEST-I\)](#).

^e Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in the presence of thoracic symptoms.

^m Patients who undergo RPLND and are found to have pN0 disease or pN1 pure teratoma need only 1 CT scan at postoperative month 3–4 and then as clinically indicated. [See Discussion](#).

ⁿ Patients with clinical stage IIA/IIB nonseminoma who undergo primary RPLND and are found to have pN0 disease (no cancer and no teratoma, pathologic stage I) should revert to the surveillance schedule for low-risk NSGCT with the exception that only 1 CT scan is needed postoperatively around month 4 (Table 5).

^o This schedule assumes a complete resection has taken place.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF RADIOTHERAPY FOR PURE TESTICULAR SEMINOMA

General Principles

- Modern radiotherapy involves smaller fields and lower doses than were used in the past. References are provided to support current recommended management.
- The mean dose (Dmean) and dose delivered to 50% of the volume (D50%) of the kidneys, liver, and bowel are lower with CT-based anteroposterior-posteroanterior (AP-PA) three-dimensional conformal radiation therapy (3D-CRT) than intensity-modulated radiation therapy (IMRT).¹ As a result, the risk of second cancers arising in the kidneys, liver, or bowel may be lower with 3D-CRT than IMRT, and IMRT is not necessary.²
- Timing of Radiotherapy:
 - ▶ Radiotherapy should start once the orchiectomy wound has fully healed.
 - ▶ Patients should be treated 5 days per week.
 - ▶ Patients who miss a fraction should be treated with the same total dose and with the same fraction size, extending the overall treatment time slightly.
- Antiemetic medication significantly improves nausea. [See the NCCN Guidelines for Antiemesis](#). Antiemetic prophylaxis is encouraged at least 2 hours prior to each treatment, and some cases may require more frequent dosing.

Preparation for Radiotherapy

- A discussion of semen analysis and sperm banking prior to orchiectomy is recommended in patients who wish to preserve fertility.^{3,4}
- If sperm banking is desired, it should be performed prior to imaging and the delivery of adjuvant therapy.

General Treatment Information

• Treatment Planning Principles

- ▶ A non-contrast CT simulation should be performed with the patient supine, arms at the patient's sides, in the treatment position.
 - ◊ Immobilization with a cast may be used to improve the reproducibility of patient setup.
 - ◊ All patients, with the exception of those who have undergone bilateral orchiectomy, should be treated with a scrotal shield.

[Stage I \(TEST-C 2 of 5\)](#)
[Stage IIA, IIB \(TEST-C 3 of 5\)](#)

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

PRINCIPLES OF RADIOTHERAPY FOR PURE TESTICULAR SEMINOMA

Stage I

- **Dose:** For stages IA, IB: Recommended radiation dose regimens are listed in the table below for the minority of patients who prefer adjuvant treatment, realizing that there is a high likelihood of salvage should a relapse occur during surveillance.⁵

Table 1

Total Dose (Gy)	Dose per Fraction (Gy)	Number of Fractions
20 (preferred)	2.0	10
25.5	1.5	17
19.8	1.8	11
21.6	1.8	12

• Para-aortic-Strip Fields⁶ - Field Arrangement:

- ▶ In patients with no history of pelvic or scrotal surgery, para-aortic strip irradiation may be delivered with opposed AP-PA fields. The weights of the fields may be equal.
 - ◊ Recent nodal mapping studies suggest that fields should target the retroperitoneal lymph nodes but not necessarily the ipsilateral renal hilar nodes (see Lateral borders).^{7,8}
 - ◊ Superior and inferior borders: Borders may be determined by bony anatomy.
 - ◊ The superior border should be placed at the bottom of vertebral body T10/T11.⁹
 - ◊ The inferior border should be placed at the inferior border of vertebral body L5.^{6,10}
 - ◊ Lateral borders:
 - Conventionally, para-aortic-strip fields are approximately 10 cm wide, encompassing the tips of the transverse processes of the PA vertebrae.
 - ◊ The location of the kidneys within the para-aortic-strip fields varies from patient to patient.
 - For patients whose kidneys are relatively medial, small renal blocks may be added at the level of T12. The right and left kidney D50% should be ≤8 Gy (ie, no more than 50% of each kidney can receive ≥8 Gy).¹ If only one kidney is present, the kidney D15% should be ≤20 Gy (ie, no more than 15% of the volume of the kidney can receive ≥20 Gy).¹
 - An alternative 3D-CRT planning technique is to base the lateral borders on vascular structures on a treatment planning CT scan without contrast. The aorta and inferior vena cava (IVC) may be contoured on the CT scan; one should allow a 1.2- to 1.9-cm margin on the aorta and IVC to include the para-aortic, paracaval, interaortocaval, and preaortic nodes in the clinical target volume.^{7,11} The planning target volume is then established by uniformly expanding the clinical target volume by 0.5 cm in all directions to account for treatment setup errors.¹² A uniform 0.7-cm margin should be provided on the planning target volume to the block edge to take beam penumbra into account (Figure 1, see [TEST-C 4 of 5](#)).¹

Special Considerations

- Ipsilateral pelvic surgery (eg, inguinal herniorrhaphy or orchiopexy) may alter the lymphatic drainage of the testis. As a result, irradiation of the ipsilateral iliac and inguinal lymph nodes, including the surgical scar from prior surgery, has been advocated even in stage I patients.^{8,13}

[Stage IIA–IIB \(TEST-C 3 of 5\)](#)
[References](#)

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

TEST-C
2 OF 5

NCCN Guidelines Version 2.2022

Testicular Cancer - Pure Seminoma

Stage II

PRINCIPLES OF RADIOTHERAPY FOR PURE TESTICULAR SEMINOMA

- Patients should not receive primary RT if they have a horseshoe (pelvic) kidney, inflammatory bowel disease, or a history of RT.
- For clinical stage IIA–B patients, treatment is delivered in two consecutive AP-PA phases (modified dog-leg fields and cone down). There is no break between the two phases.
- Modified Dog-Leg Fields:

► Dose:

- ◊ The initial phase consists of treatment of modified dog-leg fields to 20–25.5 Gy (see [Table 1 on TEST-C 2 of 5](#) for dose fractionation options).
- ◊ Boost gross disease to achieve a total dose of approximately:

Table 2: Boost to Gross Disease

Stage	Total Dose (Gy)	Dose per Fraction (Gy)
IIA	30	1.8–2.0 Gy per fraction
IIB	36	1.8–2.0 Gy per fraction

- Target: The fields should include the retroperitoneal and proximal ipsilateral iliac lymph nodes.

- ◊ Modified dog-leg fields as described by Classen et al. are preferred.¹⁴
- ◊ Care should be taken to ensure coverage of the ipsilateral common, external, and proximal internal iliac lymph nodes down to the top of the acetabulum.
- ◊ The fields can be set up using bony landmarks or by contouring the vascular structures, as for stage I.
 - The superior border should be placed at the bottom of vertebral body T10/T11.¹⁵
 - The inferior border should be placed at the top of the acetabulum.¹⁴
 - The medial border for the lower aspect of the modified dog-leg fields extends from the tip of the contralateral transverse process of the fifth lumbar vertebra toward the medial border of the ipsilateral obturator foramen.
 - The lateral border for the lower aspect of the modified dog-leg fields is defined by a line from the tip of the ipsilateral transverse process of the fifth lumbar vertebra to the superolateral border of the ipsilateral acetabulum.
 - Preferably, one should contour the aorta and IVC from the bottom of the T10/T11 vertebra inferiorly and ipsilateral iliac arteries and veins down to the top of the acetabulum. One should provide a 1.2- to 1.9-cm margin on these vascular structures for the clinical target volume.^{7,11} The planning target volume is then established by uniformly expanding the clinical target volume by 0.5 cm in all directions to account for treatment setup errors.¹² A uniform 0.7-cm margin should be provided on the planning target volume to the block edge to take beam penumbra into account (Figure 2, see [TEST-C 4 of 5](#)).¹
 - It is not necessary to include the ipsilateral inguinal nodes or the inguinal scar in the AP-PA fields unless the patient has a history of ipsilateral pelvic surgery (eg, inguinal herniorrhaphy or orchiopexy).

• Cone Down:

- Dose: The second phase (cone down) of the radiotherapy consists of daily 1.8–2 Gy fractions to a cumulative total dose of approximately 30 Gy for stage IIA and 36 Gy for stage IIB.¹⁴
- Target: The nodal mass (gross tumor volume) must be contoured. A uniform, 2-cm margin from the gross tumor volume to block edge should be provided for the AP-PA cone down fields. (Figure 3, see [TEST-C 4 of 5](#)).

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer

RISK CLASSIFICATION FOR ADVANCED DISEASE (post-orchietomy)^{a,b}

Risk Status	Nonseminoma	Seminoma
Good Risk	Testicular or retroperitoneal primary tumor ^c and No nonpulmonary visceral metastases and <u>Post-orchietomy markers</u> - all of: AFP < 1,000 ng/mL hCG < 5,000 iu/L LDH < 1.5 x upper limit of normal	Any primary site and No nonpulmonary visceral metastases and Normal AFP Any hCG Any LDH ^d
Intermediate Risk	Testicular or retroperitoneal primary tumor ^c and No nonpulmonary visceral metastases and <u>Post-orchietomy markers</u> - any of: AFP 1,000–10,000 ng/mL hCG 5,000–50,000 iu/L LDH 1.5–10 x upper limit of normal	Any primary site and Nonpulmonary visceral metastases and Normal AFP Any hCG Any LDH
Poor Risk	Mediastinal primary tumor ^c or Nonpulmonary visceral metastases or <u>Post-orchietomy markers</u> - any of: AFP > 10,000 ng/mL hCG > 50,000 iu/L LDH > 10 x upper limit of normal	No patients classified as poor prognosis

Source: Figure 4 from the International Germ Cell Cancer Collaborative Group: International Germ Cell Consensus Classification: A Prognostic Factor-Based Staging System for Metastatic Germ Cell Cancers. J Clin Oncol 1997;15:594-603. Reprinted with permission of the American Society of Clinical Oncology.

^a Markers used for risk classification are post-orchietomy.

^b Newer risk model to give prognostic information can be used through nomogram: <https://eortc.shinyapps.io/IGCCCG-Update/> (Gillesen S, et al. J Clin Oncol 2021;39:1563-1574).

^c Referral to a high-volume center is recommended for patients with extragonadal germ cell tumors. [See Discussion](#).

^d Patients with good-risk disseminated seminoma with an LDH >2.5 x ULN have a worse prognosis than other good-risk patients. However, there are insufficient data at this time to recommend treating these patients differently based on LDH.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRIMARY CHEMOTHERAPY REGIMENS FOR GERM CELL TUMORS

Preferred Regimens

• BEP

Etoposide 100 mg/m² IV on Days 1–5

Cisplatin 20 mg/m² IV on Days 1–5

Bleomycin 30 units IV weekly on Days 1, 8, and 15 or Days 2, 9, and 16

Repeat every 21 days¹

• EP

(Option only for good-risk patients [\[see TEST-D\]](#), patients with pathologic stage II disease, and patients with viable germ cell tumor at surgery following first-line chemotherapy)

Etoposide 100 mg/m² IV on Days 1–5

Cisplatin 20 mg/m² IV on Days 1–5

Repeat every 21 days²

Other Recommended Regimens

• VIP³

(Option only for intermediate or poor-risk patients or patients with viable germ cell tumor at surgery following first-line chemotherapy)

[\[See TEST-5 and TEST-11\]](#)

Etoposide 75 mg/m² IV on Days 1–5

Ifosfamide 1200 mg/m² on Days 1–5 with mesna protection

Cisplatin 20 mg/m² IV on Days 1–5

Repeat every 21 days⁴

Randomized comparison of cisplatin and etoposide and either bleomycin or ifosfamide in treatment of advanced disseminated germ cell tumors: An Eastern Cooperative Oncology Group, Southwest Oncology Group, and Cancer and Leukemia Group B Study. J Clin Oncol 1998;16:1287-1293.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

SECOND-LINE CHEMOTHERAPY REGIMENS FOR METASTATIC GERM CELL TUMORS

Conventional-Dose Chemotherapy Regimens

Preferred Regimens

- **TIP¹**
Paclitaxel 250 mg/m² IV on Day 1
Ifosfamide 1500 mg/m² IV on Days 2–5 with mesna protection
Cisplatin 25 mg/m² IV on Days 2–5
Repeat every 21 days²
- **VeIP¹**
Vinblastine 0.11 mg/kg IV Push on Days 1–2
Ifosfamide 1200 mg/m² IV on Days 1–5 with mesna protection
Cisplatin 20 mg/m² IV on Days 1–5
Repeat every 21 days³

High-Dose Chemotherapy Regimens

Preferred Regimens

- **Carboplatin/etoposide**
Carboplatin 700 mg/m² (body surface area) IV
Etoposide 750 mg/m² IV
Administer 5, 4, and 3 days before peripheral blood stem cell infusion for 2 cycles⁴
- **Paclitaxel/ifosfamide/carboplatin/etoposide**
Paclitaxel 200 mg/m² IV over 24 hours on Day 1
Ifosfamide 2000 mg/m² over 4 hours with mesna protection on Days 2–4
Repeat every 14 days for 2 cycles followed by
Carboplatin AUC 7–8 IV over 60 minutes on Days 1–3
Etoposide 400 mg/m² IV on Days 1–3
Administer with peripheral blood stem cell support at 14- to 21-day intervals for 3 cycles⁵

¹ TIP, VeIP: These regimens are high risk for febrile neutropenia and G-CSFs should be used ([See NCCN Guidelines for Hematopoietic Growth Factors](#)).

² Kondagunta GV, Bacik J, Donadio A, et al. Combination of paclitaxel, ifosfamide, and cisplatin is an effective second-line therapy for patients with relapsed testicular germ cell tumors. J Clin Oncol 2005;23:6549-6555.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**THIRD-LINE CHEMOTHERAPY REGIMENS FOR METASTATIC GERM CELL TUMORS^a****High-Dose Chemotherapy NOT Previously Received****Preferred Regimens (High-Dose Chemotherapy)**

- **Carboplatin/etoposide**
Carboplatin 700 mg/m² (body surface area) IV
Etoposide 750 mg/m² IV
Administered 5, 4, and 3 days before peripheral blood stem cell infusion for 2 cycles¹
- **Paclitaxel/ifosfamide/carboplatin/etoposide**
Paclitaxel 200 mg/m² IV over 24 hours on Day 1
Ifosfamide 2000 mg/m² over 4 hours with mesna protection on Days 2–4
Repeat every 14 days for 2 cycles followed by
Carboplatin AUC 7–8 IV over 60 minutes on Days 1–3
Etoposide 400 mg/m² IV on Days 1–3
Administered with peripheral blood stem cell support at 14- to 21-day intervals for 3 cycles²

Other Recommended Regimens

- **Gemcitabine/paclitaxel/oxaliplatin³**
Gemcitabine 800 mg/m² IV over 30 minutes on Days 1 and 8
Paclitaxel 80 mg/m² IV over 60 minutes on Days 1 and 8
Oxaliplatin 130 mg/m² IV over 2 hours on Day 1
Administered on a 21-day cycle for 8 cycles
- **Gemcitabine/oxaliplatin⁴⁻⁶**
Gemcitabine 1000–1250 mg/m² IV over 30 minutes on Days 1 and 8
followed by
Oxaliplatin 130 mg/m² IV over 2 hours on Day 1
Administered on a 21-day cycle until disease progression or unacceptable toxicity
- **Gemcitabine/paclitaxel^{7,8}**
Gemcitabine 1000 mg/m² IV over 30 minutes on Days 1, 8, and 15
Paclitaxel 100 mg/m² IV over 60 minutes on Days 1, 8, and 15
Administered on a 28-day cycle for 6 cycles
- **Etoposide (oral)⁹**
Etoposide 50–100 mg PO daily on Days 1–21
Administered on a 28-day cycle until disease progression or unacceptable toxicity

Useful in Certain Circumstances

- **Pembrolizumab (for MSI-H/dMMR or TMB-H tumors)^{b,10,11,12}**
Pembrolizumab 200 mg IV over 30 minutes on Day 1
Administered on a 21-day cycle until disease progression or unacceptable toxicity or up to 24 months
Pembrolizumab 400 mg IV over 30 minutes on Day 1
Administered on a 42-day cycle until disease progression or unacceptable toxicity or up to 24 months¹³

^a If VeIP or TIP received as second-line therapy, high-dose chemotherapy is the preferred third-line option.^b Tumor mutational burden-high (TMB-H) [≥10 mutations/megabase (mut/Mb)] tumors, as determined by a validated and/or FDA-approved comprehensive genomic profiling (CGP) assay.**Note:** All recommendations are category 2A unless otherwise indicated.**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

THIRD-LINE CHEMOTHERAPY REGIMENS FOR METASTATIC GERM CELL TUMORS^a High-Dose Chemotherapy Previously Received

Preferred Regimens

- **Gemcitabine/paclitaxel/oxaliplatin³**
Gemcitabine 800 mg/m² IV over 30 minutes on Days 1 and 8
Paclitaxel 80 mg/m² IV over 60 minutes on Days 1 and 8
Oxaliplatin 130 mg/m² IV over 2 hours on Day 1
Administered on a 21-day cycle for 8 cycles
- **Gemcitabine/oxaliplatin⁴⁻⁶**
Gemcitabine 1000–1250 mg/m² IV over 30 minutes on Days 1 and 8
followed by
Oxaliplatin 130 mg/m² IV over 2 hours on Day 1
Administered on a 21-day cycle until disease progression or unacceptable toxicity
- **Gemcitabine/paclitaxel^{7,8}**
Gemcitabine 1000 mg/m² IV over 30 minutes on Days 1, 8, and 15
Paclitaxel 100 mg/m² IV over 60 minutes on Days 1, 8, and 15
Administered on a 28-day cycle for 6 cycles
- **Etoposide (oral)⁹**
Etoposide 50–100 mg PO daily on Days 1–21
Administered on a 28-day cycle until disease progression or unacceptable toxicity

Useful in Certain Circumstances

- **Pembrolizumab (for MSI-H/dMMR or TMB-H tumors)^{b,10,11,12}**
Pembrolizumab 200 mg IV over 30 minutes on Day 1
Administered on a 21-day cycle until disease progression or unacceptable toxicity or up to 24 months
Pembrolizumab 400 mg IV over 30 minutes on Day 1
Administered on a 42-day cycle until disease progression or unacceptable toxicity or up to 24 months¹³

^a If VeIP or TIP received as second-line therapy, high-dose chemotherapy is the preferred third-line option.

^b Tumor mutational burden-high (TMB-H) [≥10 mutations/megabase (mut/Mb)] tumors, as determined by a validated and/or FDA-approved CGP assay.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF SURGERY FOR GERM CELL TUMORS

- **Radical inguinal orchiectomy is the gold standard for the diagnosis and initial management of a suspected testicular cancer. Trans-scrotal orchiectomy is discouraged as scrotal violation is associated with higher rates of local recurrence and altered pathways of metastatic dissemination.**
- **A template dissection or a nerve-sparing approach to minimize the risk of ejaculatory disorders should be considered in patients undergoing primary RPLND for stage I nonseminoma.**
- **The “split and roll” technique in which lumbar vessels are identified and sequentially ligated allows resection of all lymphatic tissue around and behind the great vessels (ie, aorta, IVC) and minimizes the risk of an in-field recurrence.**

Testis-Sparing Surgery (TSS)

- **TSS, such as partial orchiectomy, can be considered in select patients with a testicular mass.**
 - ▶ **Indications for TSS:**
 - ◊ **Synchronous bilateral germ cell tumors, a solitary testicle with a mass suspicious for germ cell tumor, or a functionally solitary testicle (eg, history of contralateral testicular atrophy). These patients should be counseled regarding the following:**
 - **High risk of local recurrence with TSS**
 - **Need for continued surveillance with testicular self-exam, physical exam by a physician, and/or ultrasound**
 - **Role of adjuvant radiation to reduce the risk of local recurrence**
 - **Impact of radiation therapy on sperm and testosterone production**
 - **Risk of testicular atrophy, need for testosterone replacement, and/or infertility**
 - ◊ **Non-palpable testicular masses <2 cm are associated with benign tumors in up to 80% of patients, and therefore, TSS may be considered in these patients in whom TSS is technically feasible.**
 - ▶ **Principles of TSS:**
 - ◊ **TSS should be performed through an inguinal approach.**
 - ◊ **Frozen section should be performed at the time of surgery by an experienced genitourinary pathologist.**
 - ◊ **Radical orchiectomy in the setting of a normal contralateral testicle is recommended if biopsy shows testicular cancer is present or there is suspicion of cancer.**

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF SURGERY FOR GERM CELL TUMORS

Postchemotherapy Setting

- **Referral to high-volume centers should be considered for surgical resection of masses postchemotherapy.**
- **Completeness of resection is a consistent independent predictor of clinical outcome. In postchemotherapy RPLND, surgical margins should not be compromised in an attempt to preserve ejaculation. Additional procedures and resection of adjacent structures may be required.**
- **Postchemotherapy RPLND is indicated in patients with metastatic NSGCT with a residual retroperitoneal mass following systemic chemotherapy and normalized postchemotherapy serum tumor markers.**
- **A full bilateral template RPLND should be performed in all patients undergoing RPLND in the postchemotherapy setting, with the boundaries of dissection being the renal hilar vessels (superiorly), ureters (laterally), and the common iliac arteries (inferiorly).**
 - ▶ **Modified template RPLND may be an option in select patients with initial stage IIA/B disease within the primary landing zones.**
- **Limited data suggest increased frequency of aberrant recurrences with the use of minimally invasive laparoscopic or robotic approaches to RPLND. Therefore, minimally invasive RPLND is not recommended as standard management, but can be considered in highly selected cases at high-volume centers.¹**

¹ Calaway AC, Einhorn LH, Masterson TA, et al. Adverse surgical outcomes associated with robotic retroperitoneal lymph node dissection among patients with testicular cancer. Eur Urol 2019;76:607-609.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**PRINCIPLES OF IMAGING****Staging****Pure Seminoma and Nonseminoma**

- Abdominal/pelvic CT scan with contrast and chest x-ray or CT scan is recommended within 4 weeks prior to the initiation of chemotherapy to confirm staging, even if scan was performed previously. ([TEST-3](#), [TEST-7](#))
 - ▶ Chest CT should be performed if abdominal/pelvic CT or chest x-ray is abnormal.

Treatment Response Assessment**Pure Seminoma**

- Consider PET/CT scan (skull base to mid-thigh) for a residual mass >3 cm post primary chemotherapy. ([TEST-5](#))
- PET/CT scan should be performed at least 6 weeks following completion of chemotherapy.
 - ▶ A negative PET/CT following chemotherapy is very reassuring. If PET/CT scan is positive, resection or interventional radiology-guided biopsy should be considered. An alternative is to wait an additional 8–12 weeks and repeat PET/CT scan to assess for changes. If the mass is persistently FDG-avid on PET, then resection or biopsy is recommended.

Surveillance**Pure Seminoma and Nonseminoma ([TEST-A](#) and [TEST-B](#))**

- MRI with contrast can be considered in select circumstances in place of an abdominal/pelvic CT.
 - ▶ MRI protocol should include visualization of retroperitoneal and pelvic nodes.
- Use the same imaging modality (CT or MRI) throughout surveillance.
- In stage I seminoma and nonseminoma, chest x-rays should be obtained when abdominal/pelvic CT scans are performed. Additional chest imaging is not indicated under normal circumstances. In a retrospective review of nearly 560 patients, 76 patients relapsed with only four patients having disease in the chest, one of whom had an abnormal chest x-ray (but also in the setting of an elevated AFP).¹ Similar data from Daugaard et al showed no role for chest x-ray in detecting relapse.² Other series have also called into question the value of chest x-rays in this and other surveillance settings for germ cell tumors.^{3,4}

¹ De La Pena H, Sharma A, Glicksman C, et al. No longer any role for routine follow-up chest x-rays in men with stage I germ cell cancer. Eur J Cancer 2017;84:354-359.

³ Tolan S, Vesprini D, Jewett MA, et al. No role for routine chest radiography in stage I seminoma surveillance. Eur Urol 2010;57:474-479.

⁴ Gietema JA, Meinardi MT, Sleijfer DT, et al. Routine chest X-rays have no additional value in the detection of relapse during routine follow-up of patients treated with chemotherapy for disseminated non-seminomatous testicular cancer. Ann Oncol 2002;13:1616-1620.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

American Joint Committee on Cancer (AJCC) TNM Staging Classification for Testis Cancer 8th ed., 2017

Table 1. Definitions for T, N, M

Clinical T Primary Tumor

cTX	Primary tumor cannot be assessed
cT0	No evidence of primary tumor
cTis	Germ cell neoplasia <i>in situ</i>
cT4	Tumor invades scrotum with or without vascular/lymphatic invasion

Note: Except for Tis confirmed by biopsy and T4, the extent of the primary tumor is classified by radical orchiectomy. TX may be used for other categories for clinical staging.

Pathological T Primary Tumor

pTX	Primary tumor cannot be assessed
pT0	No evidence of primary tumor
pTis	Germ cell neoplasia <i>in situ</i>
pT1	Tumor limited to testis (including rete testis invasion) without lymphovascular invasion
pT1a*	Tumor smaller than 3 cm in size
pT1b*	Tumor 3 cm or larger in size
pT2	Tumor limited to testis (including rete testis invasion) with lymphovascular invasion OR Tumor invading hilar soft tissue or epididymis or penetrating visceral mesothelial layer covering the external surface of tunica albuginea with or without lymphovascular invasion
pT3	Tumor directly invades spermatic cord soft tissue with or without lymphovascular invasion
pT4	Tumor invades scrotum with or without lymphovascular invasion

***Subclassification of pT1 applies to only pure seminoma.**

American Joint Committee on Cancer (AJCC) TNM Staging Classification for Testis Cancer 8th ed., 2017

Table 1 (continued)

Clinical N	Regional Lymph Nodes	M	Distant Metastasis
cNX	Regional lymph nodes cannot be assessed	M0	No distant metastases
cN0	No regional lymph node metastasis	M1	Distant metastases
cN1	Metastasis with a lymph node mass 2 cm or smaller in greatest dimension OR Multiple lymph nodes, none larger than 2 cm in greatest dimension	M1a	Non-retroperitoneal nodal or pulmonary metastases
		M1b	Non-pulmonary visceral metastases
cN2	Metastasis with a lymph node mass larger than 2 cm but not larger than 5 cm in greatest dimension OR Multiple lymph nodes, any one mass larger than 2 cm but not larger than 5 cm in greatest dimension	S	Serum Markers
cN3	Metastasis with a lymph node mass larger than 5 cm in greatest dimension	SX	Marker studies not available or not performed
		S0	Marker study levels within normal limits
		S1	LDH <1.5 x N* and hCG (mIU/mL) <5,000 and AFP (ng/mL) <1,000
		S2	LDH 1.5–10 x N* or hCG (mIU/mL) 5,000–50,000 or AFP (ng/mL) 1,000–10,000
		S3	LDH >10 x N* or hCG (mIU/mL) >50,000 or AFP (ng/mL) >10,000
Pathological N	Regional Lymph Nodes		
pNX	Regional lymph nodes cannot be assessed		
pN0	No regional lymph node metastasis		
pN1	Metastasis with a lymph node mass 2 cm or smaller in greatest dimension and less than or equal to five nodes positive, none larger than 2 cm in greatest dimension		
pN2	Metastasis with a lymph node mass larger than 2 cm but not larger than 5 cm in greatest dimension; or more than five nodes positive, none larger than 5 cm; or evidence of extranodal extension of tumor		
pN3	Metastasis with a lymph node mass larger than 5 cm in greatest dimension		

* N indicates the upper limit of normal for the LDH assay.

NCCN Categories of Evidence and Consensus

Category 1	Based upon high-level evidence, there is uniform NCCN consensus that the intervention is appropriate.
Category 2A	Based upon lower-level evidence, there is uniform NCCN consensus that the intervention is appropriate.
Category 2B	Based upon lower-level evidence, there is NCCN consensus that the intervention is appropriate.
Category 3	Based upon any level of evidence, there is major NCCN disagreement that the intervention is appropriate.

All recommendations are category 2A unless otherwise indicated.

NCCN Categories of Preference

Preferred intervention	Interventions that are based on superior efficacy, safety, and evidence; and, when appropriate, affordability.
Other recommended intervention	Other interventions that may be somewhat less efficacious, more toxic, or based on less mature data; or significantly less affordable for similar outcomes.
Useful in certain circumstances	Other interventions that may be used for selected patient populations (defined with recommendation).

All recommendations are considered appropriate.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 2.2022

Testicular Cancer

Overview

Testicular cancer is relatively uncommon and accounts for less than 1% of all male tumors.¹ However, it is the most common solid tumor in males between ages 20 and 34 years, and the global incidence has been steadily rising over the past several decades.¹⁻⁸ An estimated 9470 new cases of testicular cancer will be diagnosed in the United States in 2021 resulting in approximately 440 deaths, which reflects the excellent 5-year survival rate for this disease (~95%).^{1,9} Several risk factors for testicular cancer have been identified, including personal or family history of testicular cancer and cryptorchidism.^{2,10,11}

Testicular germ cell tumors (GCTs) comprise 95% of malignant tumors arising in the testes and are categorized into two main histologic subtypes: seminoma and nonseminoma.^{2,12,13} Nonseminomas are less common, but are more aggressive and often include multiple cell types. When both seminoma and elements of nonseminoma are present, management follows that of a nonseminoma. The four types of nonseminomas are embryonal carcinoma, choriocarcinoma, yolk sac tumor, and teratoma.¹² Most nonseminomas are mixed tumors of these four subtypes. Teratomas are sometimes classified as either mature or immature, but this distinction is of no known significance in adult males and does not affect management in these patients. Rarely, a teratoma may contain elements of a somatic cancer, such as a sarcoma or adenocarcinoma, and is then referred to as a teratoma with somatic-type malignancy. Teratomas with somatic-type malignancy are managed differently from other GCTs. Prepubertal teratomas, which are biologically different from the much more common post-pubertal teratomas, are occasionally diagnosed in adults and are less aggressive and managed differently.^{14,15}

Rarely, GCTs may originate in extragonadal sites (usually the retroperitoneum or mediastinum). Patients with an extragonadal primary site are managed similarly to patients with testicular GCTs regarding

systemic therapies and management of residual masses.¹⁶ However, due to their rarity, the NCCN Panel recommends that patients with extragonadal GCTs be referred to high-volume centers with experience in managing these tumors.

The serum tumor markers alpha-fetoprotein (AFP) and beta-human chorionic gonadotropin (beta-hCG) are critical in determining prognosis and assessing treatment outcomes in patients with testicular GCTs. Levels of these serum tumor markers should be determined before and after treatment and throughout the follow-up period. Marker levels are very useful for monitoring all stages of nonseminomas and are also useful in monitoring stage II and III seminomas, because elevated marker levels may be an early sign of relapse. In addition, lactate dehydrogenase (LDH) is important for determining prognosis and is used to help risk stratify patients starting first-line chemotherapy for disseminated nonseminomatous tumors.¹⁷ Although serum LDH concentrations are elevated in approximately 50% of patients with advanced testicular cancer, LDH is a less specific marker for testicular cancer compared to AFP and beta-hCG. Therefore, decisions regarding treatment should not be made based on mildly elevated (<3 x upper limit of normal [ULN]) LDH alone. LDH has not been used in the past to risk stratify patients with disseminated pure seminoma; however, a 2021 study reported that an LDH above 2.5 times the ULN was associated with worse prognosis in patients with otherwise good-risk disease.¹⁸

Beta-hCG is the most commonly elevated serum tumor marker in testicular cancer. Elevated serum concentrations of beta-hCG may be present with both seminomatous and nonseminomatous tumors. However, in patients with seminoma with beta-hCG levels greater than 1000 IU/L, the possibility of nonseminoma should be considered and the surgical specimen with pathology should be re-reviewed. Referral to a high-volume center experienced in the management of these patients should also be considered. Additionally, patients with post-orchietomy beta-hCG levels

NCCN Guidelines Version 2.2022

Testicular Cancer

greater than 5000 IU/L should receive a brain MRI since they are at an increased risk of having brain metastases. Further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L), since other factors such as hypogonadism, hyperthyroidism, and marijuana use can cause elevations of beta-hCG.¹⁹⁻²¹ Intramuscular injection of 300 mg of testosterone cypionate may be administered in cases of mild beta-hCG elevations of unclear etiology to exclude hypogonadism as a cause. Elevated beta-hCG has also been reported in other tumors, such as lymphoma, bladder cancer, and adenocarcinomas, and is thus not specific for GCTs.²² Additionally, heterophile antibodies have been reported to result in substantially elevated false-positive beta-hCG results (>400 IU/L); therefore, clinicians should consider repeating the test using a different assay if a false positive is suspected due to the absence of radiographic evidence of disease.²³⁻²⁵

Elevated serum AFP is not associated with pure seminoma. Among nonseminoma GCTs, it is particularly associated with yolk sac tumors but can also be produced by embryonal carcinomas and teratoma. When patients with a histologically “pure” seminoma have an elevated level of AFP, it is generally interpreted as meaning the tumor is a mixed GCT and that undetected nonseminomatous GCT elements are present in addition to the seminoma.^{17,26-28} Therefore, the diagnosis of a seminoma is restricted to pure seminoma histology and normal serum AFP levels. However, a small number of people have a chronically elevated serum AFP level and clinicians should be cautious about initiating treatment for a mildly elevated but stable AFP.²⁹ In addition, other tumors such as hepatocellular carcinomas and gastric carcinomas can cause AFP elevation. If an elevation of serum AFP is due to a metastatic nonseminomatous GCT, then the AFP typically will be steadily rising. Generally, decisions to treat should not be based solely on AFP values less than 20 ng/mL.

These guidelines pertain to all stages of testicular GCTs and should be closely followed to maximize the potential for cure and to avoid unnecessary side effects, complications, and late toxicities. It is important to note that pediatric GCTs are managed differently from adult GCTs and are not covered in these guidelines. Additionally, testicular tumors arising from the stroma are also not covered in these guidelines. They account for less than 5% of cases and have a different biology and natural history.

Literature Search Criteria and Guidelines Update Methodology

Prior to the update of this version of the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) Testicular Cancer, an electronic search of the PubMed database was performed using the following search terms: ‘testicular cancer’ and ‘germ cell tumor.’ The PubMed database was chosen as it remains the most widely used resource for medical literature and indexes peer-reviewed biomedical literature.³⁰

The search results were narrowed by selecting studies in humans published in English. Results were confined to the following article types: Clinical Trial, Phase II; Clinical Trial, Phase III; Clinical Trial, Phase IV; Guideline; Randomized Controlled Trial; Meta-Analysis; Systematic Reviews; and Validation Studies.

The data from key PubMed articles as well as articles from additional sources deemed as relevant to these Guidelines and/or discussed by the panel have been included in this version of the Discussion section (eg, e-publications ahead of print, meeting abstracts). Any recommendations for which high-level evidence is lacking are based on the panel’s review of lower-level evidence and expert opinion.

The complete details of the development and update of the NCCN Guidelines are available at www.NCCN.org.

NCCN Guidelines Version 2.2022

Testicular Cancer

Clinical Presentation, Workup, and Primary Treatment

Clinical Presentation

Testicular cancer most often presents as a painless or painful testicular nodule, mass, enlargement, or induration (hardening). Often, patients will present with testicular discomfort or swelling suggestive of epididymitis or orchitis. A trial of antibiotics is never warranted in the treatment of a mass suspicious for GCT, but can be considered in patients with pain without a mass on further workup. Other patients may present with enlarged lymph nodes of the lower neck or upper chest (supraclavicular), a retroperitoneal mass, gynecomastia, venous thrombosis, or pulmonary embolism.

Workup

If testicular cancer is being considered as a possibility, then a transscrotal ultrasound with Doppler should be performed. Testicular ultrasound can confirm the presence of a testicular mass, determine whether a mass is intra- or extratesticular, and explore the contralateral testis.³¹ Testicular GCTs are typically heterogeneous, hypoechoic, and vascular on ultrasound. If the ultrasound findings show a mass suspicious for malignancy, then a radical inguinal orchiectomy is generally performed to make a diagnosis. Testis-sparing surgery (ie, partial orchiectomy) may be considered in select patients (See *Principles of Surgery* TEST-H 1 of 2 in the algorithm). Unique clinical settings that warrant consideration for testis-sparing surgery include synchronous bilateral tumors, a solitary testicle with a mass suspicious for GCT, a functionally solitary testicle (eg, history of contralateral testicular atrophy), radiographically benign-appearing tumors, or non-palpable tumors less than 2 cm.³²⁻³⁴ Transscrotal biopsies of the testes should not be performed because violating the scrotum increases the risk of local or atypical regional recurrence and can complicate management. In addition, a thorough history and physical examination should be performed. Serum tumor markers (LDH, AFP, and beta-hCG) also need to be assessed as they are used for prognosis and

staging.¹³ Marker levels should be assessed both before and after orchiectomy. Elevated levels of beta-hCG, LDH, or AFP should be followed up with repeated tests to allow for precise staging. Given the higher rates of hypogonadism in the testicular cancer population, measuring baseline levels of gonadal function can also be considered.

Primary Treatment

Radical inguinal orchiectomy is the primary treatment for most patients who present with a testicular mass that is suspicious for malignancy on ultrasound.³⁵ Concurrent insertion of testicular prosthesis may be considered during radical inguinal orchiectomy if desired by the patient.³⁶⁻³⁸ In cases where the ultrasound shows an ambiguous abnormality that might be malignant, an open inguinal biopsy (testis-sparing surgery or partial orchiectomy) with intraoperative frozen section analysis can be performed, but such cases are extremely rare. Reflex radical orchiectomy is recommended in most circumstances should malignancy be detected. Similarly, an open inguinal biopsy of the contralateral testis (inguinal exploration with exposure of testis, with direct observation and partial orchiectomy) can be considered if an ambiguous suspicious mass is identified on ultrasound or if the testis is cryptorchid or shows marked atrophy.³⁹ However, biopsies are not recommended for testicular microcalcifications alone.

Sperm banking should be discussed with patients of reproductive age, if clinically indicated, before undergoing any therapeutic intervention that may compromise fertility, including surgery, radiation therapy (RT), or chemotherapy.⁴⁰⁻⁴³ If sperm banking is desired, it may be performed before orchiectomy in patients with risk factors for infertility (atrophic contralateral testicle, history of infertility), but certainly should be considered prior to subsequent therapy in patients who desire future fertility.

Further management is dictated by histology, stage, and whether the cancer is a pure seminoma or a nonseminoma (includes mixed GCTs that

NCCN Guidelines Version 2.2022

Testicular Cancer

are partially comprised of seminoma and tumors that are histopathologically described as pure seminomas in patients with elevated serum AFP). Although rare, when a patient presents with: 1) markedly elevated beta-hCG or AFP levels; 2) a testicular mass and/or disease distribution typical for a testicular, retroperitoneal, or mediastinal GCT; and 3) a clinical scenario where, due to the bulk, signs, or symptoms of disease, the risk of delaying systemic therapy outweighs the benefit of a tissue diagnosis, chemotherapy may be initiated immediately without waiting for a biopsy diagnosis or performing orchiectomy. Orchiectomy should be performed after completion of chemotherapy, oftentimes at the time of retroperitoneal lymph node dissection (RPLND) or other adjunctive surgical procedures.

Staging

Staging of testicular GCTs is based on determination of the extent of disease and assessment of post-orchiectomy levels of serum tumor markers.¹³ The tumor (T), node (N), and metastasis (M) staging system used by the AJCC is the internationally accepted standard for cancer staging and is a major factor influencing prognosis and treatment decisions. The AJCC TNM staging system incorporates serum tumor marker elevation as a distinct category (S), which is unique to this organ site. The extent of the primary tumor is classified after orchiectomy; therefore, pathologic (p) staging is assigned to the primary tumor (T).

The 8th edition of the AJCC Cancer Staging Manual introduced invasion of the epididymis and hilar soft tissue as new pathologic criteria used for T classification of stage I testicular GCTs.^{13,44} Due to the excellent clinical outcomes seen in testicular cancer, large-scale follow-up studies have historically used tumor relapse rather than tumor-specific survival to validate the relevance of pathologic parameters used for staging.¹³ However, the association of hilar soft tissue and epididymal invasion with relapse of stage I disease has not been validated. Current data only

support their association with having advanced-stage disease at the time of diagnosis.^{45,46} Therefore, it is the opinion of the panel that these factors should not be used for clinical decision-making in the management of these patients. Instead, the NCCN Guidelines® for Testicular Cancer recommend managing patients with stage I nonseminoma based on the presence or absence of lymphovascular invasion (LVI), invasion of the spermatic cord, or invasion of the scrotum, which are risk factors known to be associated with an increased risk of relapse.⁴⁷⁻⁵⁶ Predominance of embryonal carcinoma has also been proposed as a prognostic indicator of relapse in stage I nonseminoma, with several studies showing that a high proportion of embryonal carcinoma in the primary tumor (>50%) is associated with an increased risk of relapse.^{49,57-64} However, very few patients have a high volume of embryonal carcinoma without also having LVI, and the value of embryonal carcinoma predominance in predicting relapse in the absence of LVI is unclear.^{49,57,60,64} Therefore, predominance of embryonal carcinoma is not used by the NCCN Guidelines for Testicular Cancer to risk stratify patients with stage I nonseminoma. Patients with stage I nonseminoma with a high volume of embryonal carcinoma and no evidence of LVI are neither high risk nor low risk and could be considered for adjuvant therapy. The NCCN Guidelines do not recommend risk-adapted treatment for stage I pure seminoma.

The 8th edition of the AJCC Cancer Staging Manual also introduced changes to pathologic staging based on the type of spermatic cord involvement. Currently, continuous involvement of the spermatic cord soft tissue by the primary tumor is staged as pT3, whereas discontinuous spermatic cord involvement by invasion of lymphovascular spaces is now considered as a metastatic deposit (pM1).¹³ This significant change results in patients with discontinuous spermatic cord involvement being upstaged from high risk stage I to stage III disease independent of radiologic or serologic assessment, which the panel is concerned may lead to overtreatment. The evidence used to support this change is unclear;

NCCN Guidelines Version 2.2022

Testicular Cancer

presently, there are no persuasive data showing differences in clinical outcomes between patients with discontinuous spermatic cord involvement compared to patients with continuous involvement. A recent retrospective analysis assessing the impact of different patterns of spermatic cord involvement on clinical stage and patient outcomes found no significant differences in either clinical stage at presentation or risk of recurrence based on the type of spermatic cord involvement (continuous vs. discontinuous).⁶⁵ Therefore, for management decisions, the panel recommends staging GCTs with discontinuous invasion of the spermatic cord as pT3 (high-risk stage I) and not as pM1 (stage III) as is recommended by the AJCC. If surveillance is elected as primary management, the pelvis should be included in the imaging due to a higher risk of pelvic relapses in these patients.

To assess for metastatic disease, imaging studies of the chest, abdomen, and pelvis should be performed. Such studies typically include CT scans of the abdomen and pelvis and CT scan or x-ray of the chest. PET scans should not be used to stage testicular GCTs. In select patients, brain MRI should also be performed; these patients include those with neurologic symptoms, post-orchietomy serum beta-hCG greater than 5000 IU/L, non-pulmonary visceral metastases, or extensive lung metastases. In patients who had elevated serum tumor markers prior to orchietomy, it is important to obtain the half-life kinetics of the tumor markers after orchietomy if the markers are declining because a slower-than-expected decline often indicates the presence of metastatic disease.

The updated 2016 World Health Organization (WHO) tumor classification scheme contains new entities for GCTs.⁶⁶ Major changes include a pathogenetically derived classification using germ cell neoplasia in situ (GCNIS) of the testis as the new WHO-recommended term for precursor lesions of invasive GCTs, and the distinction between testicular GCTs derived from GCNIS (postpubertal) and those unrelated to GCNIS (prepubertal).^{66,67} Additionally, spermatocytic seminoma has been

renamed as spermatocytic tumor, to avoid potential confusion with the unrelated usual seminoma. Presently, reporting of anaplasia (seminoma or spermatocytic tumor) or distinguishing mature from immature teratoma is not required, since these do not have demonstrable prognostic importance. Conversely, the presence of somatic-type malignancy arising in teratomas indicates more aggressive behavior, and should therefore be reported.

Risk Classification for Advanced Disease

In 1997, the International Germ Cell Cancer Consensus Group (IGCCCG) defined a classification system based on identification of clinically independent prognostic features such as extent of disease and post-orchietomy levels of serum tumor markers. This classification system categorizes patients with testicular GCTs into good-, intermediate-, or poor-risk groups.⁶⁸ When determining a patient's risk classification, the relevant serum tumor marker value is the value on day one of cycle one of first-line chemotherapy. Definitions of stage and risk classification in these guidelines are done according to the IGCCCG classifications.

The IGCCCG classification system plays a pivotal role in the management of metastatic GCTs, but relies on old data of patients treated between 1975 and 1990. The IGCCCG Update Model, published in 2021, included data from 9728 males with metastatic nonseminomatous GCTs treated with EP-based first-line chemotherapy between 1990 and 2013 at institutions in Europe, North America, and Australia.⁶⁹ Compared with the original IGCCCG publication, 5-year progression-free survival (PFS) remained similar in patients with good or intermediate risk (89% vs. 90% and 75% vs. 78%, respectively), but the 5-year overall survival (OS) increased from 92% to 96% in good-risk and from 80% to 89% in intermediate-risk patients. In poor risk patients, the 5-year PFS increased from 41% to 54% and the OS from 48% to 67%. Furthermore, a novel prognostic model for PFS was developed in 3543 patients and validated in

NCCN Guidelines Version 2.2022

Testicular Cancer

an independent dataset. This more granular prognostic model identified a new cutoff of LDH at 2.5 X ULN, increasing age, and presence of lung metastases as additional adverse prognostic factors. An online calculator is provided (<https://www.eortc.org/IGCCCG-Update>). It should be noted that patients with good risk disseminated seminoma with an LDH >2.5 X ULN have a worse prognosis than other good risk patients. However, currently there are insufficient data to recommend treating these patients differently based on LDH level.

Pure Seminoma

If a pure seminoma is detected, an abdominal/pelvic CT scan should be performed to assess the retroperitoneal lymph nodes. A chest x-ray is also recommended. A chest CT is indicated if the abdominal/pelvic CT or the chest x-ray shows evidence of metastatic disease. Measurement of beta-hCG, LDH, and AFP levels should be repeated since TNM staging is based on marker levels at the time the patient starts post-orchietomy therapy. Elevated levels should be followed with repeated measurement to allow for precise staging. Declining markers should be followed until normalization or nadir. Beta-hCG and LDH may be elevated in patients with seminoma; however, elevated LDH and beta-hCG alone should not be used to stage or risk stratify patients with pure seminoma. An elevated AFP indicates nonseminoma unless another cause of the elevated AFP (such as liver disease) is identified. Patients with seminoma arising from an extragonadal site, such as the mediastinum, are usually diagnosed via biopsy and treated with standard chemotherapy regimens according to risk classification. Brain MRI is recommended if beta-hCG levels exceed 5000 IU/L (as noted above, a beta-hCG >1000 IU/L is rare in seminoma and a value >5000 IU/L is generally indicative of a nonseminomatous GCT), if there is extensive metastatic disease in the lungs, or if non-pulmonary visceral metastases or neurologic symptoms are present. Sperm banking

should be recommended, if feasible, to patients who will be undergoing chemotherapy, RT, or RPLND if they wish to preserve fertility.

Pure Seminoma Stages IA and IB

Primary Treatment for Pure Seminoma Stages IA and IB

Since most patients with stage I pure seminoma are cured by orchiectomy alone, the NCCN Panel strongly prefers surveillance as the standard post-orchiectomy management option for these patients. However, since 15% to 20% of patients on surveillance will experience relapse, the panel recommends chemotherapy with one or two cycles of single-agent carboplatin, or RT (20 Gy or 25.5 Gy) as alternative options to decrease the risk of relapse in certain patients. Disease-specific survival for stage I disease approaches 100% irrespective of the management strategy used.⁷⁰

Surveillance: Several studies evaluating surveillance for the management of stage I seminoma have been conducted.⁷¹⁻⁷⁶ The relapse rates seen in these studies have ranged from 15% to 20%, with most disease relapse detected in the infradiaphragmatic lymph nodes. The best established risk factor for relapse of pure seminoma is increased size of the primary tumor.⁷⁷ As the tumor size increases, the risk of relapse also increases, but any cutoff point is arbitrary.^{71,73,78,79-81} Although the 8th edition of the AJCC Cancer Staging Manual uses a cutoff point of 3 cm to subclassify stage I pure seminoma, this small cutoff size was chosen in an effort to be conservative due to the large variability in size cutoffs reported in the literature.¹³ Additionally, some studies have reported that rete testis invasion is an independent risk factor for relapse in stage I pure seminoma while others have reported that it is not.^{71,73,77-79,82} A recent systematic review determined that rete testis invasion is significantly associated with risk of relapse in patients with stage I seminoma managed by surveillance.⁸² In contrast, another recent systematic review found rete

NCCN Guidelines Version 2.2022

Testicular Cancer

testis invasion to be significantly associated with relapse in only 4 of the 13 studies analyzed.⁷⁷ Due to these concerns, the NCCN Panel discourages risk-adapted management in stage I pure seminoma and instead strongly recommends surveillance for all patients who are able to adhere to the surveillance schedule. If surveillance is not applicable, alternative options are either adjuvant chemotherapy with single-agent carboplatin or adjuvant RT as described below. Each approach has distinct advantages and disadvantages that should be discussed with patients and their families to select the best individual treatment plan.

Adjuvant Chemotherapy: Oliver et al reported the initial results of a trial that randomized 1477 patients with stage I seminoma to receive either RT (n = 885) or 1 cycle of intravenous carboplatin (n = 560) at the dose area under the curve (AUC) $\times 7$ (ie, based on the formula $7 \times [\text{glomerular filtration rate (GFR, mL/min)} + 25 \text{ mg}]$).⁸³ At a follow-up of 3 years, the relapse-free survival rates for both groups were similar (95.9% for the RT group and 94.8% for the carboplatin group), which established the noninferiority of carboplatin compared to RT.⁸³ The mature results of this trial confirmed the noninferiority of single-dose carboplatin versus RT in terms of relapse-free survival.⁸⁴ In an intent-to-treat analysis, the relapse-free survival rates at 5 years were 96% in the RT arm and 94.7% in the carboplatin arm (hazard ratio [HR], 1.25; $P = .37$). One seminoma-related death occurred after RT and none occurred after carboplatin. Additionally, patients given carboplatin were less lethargic and less likely to take time off from work than patients receiving RT. Therefore, the authors concluded that a single dose of carboplatin is less toxic and as effective in preventing disease relapse as adjuvant RT in males with stage I pure seminoma after orchiectomy.⁸⁴ However, it should be noted that there are limited long-term follow-up data regarding the toxicity and efficacy of carboplatin.^{71,85} A recent non-randomized population-based study of 897 patients with stage I seminoma suggested that patients with tumor size greater than 4 cm, rete testis invasion, or both derive a smaller reduction in relapse rate with

one cycle of carboplatin than previously reported.^{71,73,85} After a median follow-up of 5.6 years, the relapse rate in patients with one or both risk factors was 15.5% for patients managed by surveillance versus 9.3% for patients who received one cycle of carboplatin.⁷¹ An absolute reduction in the risk of relapse by only 6.2% may not be sufficient to justify the use of single-cycle adjuvant carboplatin.⁸⁵ Platinum-based chemotherapy has been associated with cardiac toxicity and an increased risk for secondary cancers.⁸⁶⁻⁸⁸ However, whether such long-term risks ensue from single-agent carboplatin as dosed for seminoma remains unknown. Therefore, more data are needed to assess the value of one cycle of carboplatin in treating patients with stage I seminoma.

Use of two cycles of adjuvant carboplatin in this setting has also been studied. The Spanish Germ Cell Cancer Cooperative Group reported that among 412 males treated with two cycles of adjuvant carboplatin for high-risk stage I seminoma, the 10-year relapse-free survival rate was 97% and 10-year OS was 100%.⁸⁹⁻⁹¹ The efficacy of two cycles of adjuvant carboplatin was confirmed in a study by the Hellenic Cooperative Oncology Group, which reported a 5-year relapse-free survival rate of 96.8% among 138 patients with stage I seminoma treated with this regimen.⁹² A recent prospective study reported the treatment outcomes of 725 patients with stage I seminoma managed by surveillance, one cycle of carboplatin, or two cycles of carboplatin.⁹³ Although disease-specific survival was 100% for all three strategies, crude relapse rates were significantly higher with the one-cycle regimen (5%) compared to the two-cycle regimen (1.5%) after a median follow-up of 30 months. The crude relapse rate for surveillance was 8.2%. Furthermore, one cycle of carboplatin demonstrated low efficacy to control large tumors. Regardless of the regimen used, performing abdominal/pelvic CT scan with contrast and chest x-ray or CT scan is recommended within 4 weeks prior to the initiation of chemotherapy to confirm staging, even if scans were previously performed.

NCCN Guidelines Version 2.2022

Testicular Cancer

Adjuvant Radiation Therapy: Numerous studies have found an increased risk for late toxicities, including development of secondary malignancies, in patients with seminoma treated with RT; however, many of these patients were treated at a time when treatment fields were larger and radiation doses were higher than those currently used.^{94,95} One population-based study reported that RT for stage I seminoma was associated with an 80% increase in the risk of death from secondary cancers.⁹⁶ Another study found that moderate-dose infradiaphragmatic RT for stage I seminoma was associated with an increased risk for secondary cancers in organs within the radiation field.⁹⁷ A recent multicenter cohort study reached similar conclusions, reporting that the risk of developing an infradiaphragmatic solid malignant neoplasm increased by 8% per Gy of radiation dose administered (95% CI, 6%–9%; $P < .001$).⁸⁸ Additionally, one study reported that RT might increase the risk of a subsequent cardiac event,⁸⁶ but other analyses have not confirmed this risk.⁹⁶

Nodal mapping studies suggest that treatment fields should target the retroperitoneal lymph nodes but not necessarily the ipsilateral renal hilar nodes.^{98,99} Special circumstances, such as ipsilateral pelvic surgery, may alter the lymphatic drainage of the testis. Therefore, irradiation of the ipsilateral iliac and inguinal lymph nodes has been advocated in such patients.^{98,100,101} It should be noted that patients treated with para-aortic RT have a slightly higher rate of pelvic relapse compared with those treated with “dog-leg” RT.^{101–104} Prophylaxis to the mediastinum is not provided, because relapse rarely occurs at this site and mediastinal radiotherapy introduces additional toxicities and late effects.

The NCCN Panel prefers surveillance to the routine use of adjuvant therapy for patients with stage I seminoma because the risk of relapse is low when considered in relation to the potential harms of adjuvant therapy. However, if adjuvant chemotherapy is given, the NCCN Panel recommends carboplatin (AUC $\times 7$) for either one or two cycles for patients with stage IA or IB pure seminoma. If RT is delivered, the panel

recommends a total dose of 20 Gy be administered in 10 fractions of 2.0 Gy each.¹⁰⁵ Alternatively, a total dose of 25.5 Gy can be given in 17 fractions of 1.5 Gy each.¹⁰⁶ Other RT dose schedules are listed in the *Principles of Radiotherapy for Pure Testicular Seminoma* in the algorithm (see Table 1 on TEST-C 2 of 5). Patients at higher risk for morbidity from RT, such as those with a history of inflammatory bowel disease or prior RT, are generally not given primary RT.

Follow-up for Pure Seminoma Stages IA and IB After Primary Treatment

Although no single follow-up plan is applicable to all patients, the NCCN Panel has provided guidance for the follow-up of patients with testicular GCTs for the first 5 years after the completion of therapy. These recommendations may be individualized and extended beyond 5 years at the discretion of the physician. Follow-up strategies for patients with stage I seminoma vary according to the treatment modality received by the patient (surveillance vs. adjuvant therapy). An analysis of more than 5000 patients with stage I seminoma from various trials reported that the 5-year relapse rate was higher with surveillance (18.6%) compared to RT (4.8% with extended-field RT and 3.6% with para-aortic RT) or chemotherapy (6.1% with 1 cycle of carboplatin and 2.3% with 2 cycles of carboplatin).¹⁰³ An analysis of data from the Danish Testicular Cancer database reached similar conclusions, reporting that the 10-year cumulative incidence of disease recurrence was 32% for patients with high-risk (tumor size ≥ 6 cm) stage I seminoma given surveillance versus 2.8% for those given adjuvant RT.¹⁰⁷ An analysis of data from the National Cancer Database examined the survival outcomes of 33,094 patients with stage I seminoma who received surveillance, chemotherapy, or RT as primary treatment after orchiectomy.¹⁰⁸ Although OS was high for all strategies, results showed a small absolute survival advantage for adjuvant therapy (RT or chemotherapy) over surveillance at 10 years (95% vs. 93.4%; HR, 0.58; $P < .0005$). However, in this study, surveillance was defined as not having undergone radiation or chemotherapy, meaning that no distinction was

NCCN Guidelines Version 2.2022

Testicular Cancer

made between patients who underwent surveillance and patients who never followed up. Thus, patients for whom active treatment was recommended but who never came in for treatment would have been considered to have undergone surveillance even if they never had any surveillance visits or tests. Independent of the treatment modality received by the patient, the risk of relapse is highest in the first 2 years following treatment.¹⁰³ In the event of relapse, clinicians should keep in mind the potential for development of a second primary tumor in the contralateral testis.

Follow-up During Surveillance: Follow-up for patients with stage I seminoma managed with surveillance after orchiectomy is outlined in Table 1 on TEST-A 1 of 2 in the algorithm and includes a history and physical examination, with optional measurement of serum tumor markers, performed every 3 to 6 months for year 1, every 6 months for year 2, every 6 to 12 months for year 3, and annually for years 4 and 5.^{91,109,110} The measurement of serum tumor markers is optional due to the rarity of marker-only relapse, since most patients with elevated markers will also have evidence of relapse on imaging. Additionally, in one of the largest prospectively maintained databases of patients with stage I seminoma managed with surveillance, it was reported that routine measurement of serum tumor markers did not aid in the early diagnosis of relapse.¹¹¹ Therefore, routine measurement of serum tumor markers can be safely omitted from stage I seminoma surveillance schedules.

There is controversy regarding how many imaging studies should be performed in patients on surveillance. A phase III clinical trial in the United Kingdom entitled TRISST (MRC TE24/TRial of Imaging and Schedule in Seminoma Testis) investigated whether MRI or a reduced CT schedule could be used as a safe and effective alternative to standard CT-based surveillance in the management of stage I seminoma.¹¹² The trial randomized 669 patients with stage I seminoma post-orchiectomy to receive 7 CTs, 7 MRIs, 3 CTs, or 3 MRIs at selected intervals. After a

median follow-up of 72 months, 12% of patients had relapsed. In all groups, most relapses were detected at scheduled imaging with very few occurring beyond 3 years. Relapse treatment outcomes were good, with 81% of patients experiencing a complete response with no tumor-related deaths. Five-year disease-free survival (DFS) and OS were also similar across groups, suggesting non-inferiority of MRI or reduced CT schedule to standard CT schedule for surveillance of patients with stage I seminoma. The NCCN Panel recommends an abdominal/pelvic CT scan with or without contrast at 4 to 6 months and 12 months during year 1, every 6 months for year 2, every 6 to 12 months for year 3, and then every 12 to 24 months for years 4 and 5. CT is not recommended beyond 5 years, unless clinically indicated. The panel regards MRI as an appropriate option that can be considered to replace abdominal/pelvic CT. The MRI protocol should include visualization of all the nodes that need to be assessed, including the retroperitoneal and pelvic nodes.

Several studies have suggested that relapses in the lung are rarely detected by chest x-ray alone in patients with stage I seminoma managed by surveillance.¹¹³⁻¹¹⁵ In a recent retrospective analysis of 886 patients with stage I seminoma, 83 patients experienced relapse.¹¹⁴ All relapses were detected by either rising tumor markers and/or follow-up CT scan; not a single relapse was detected by routine chest x-ray alone. Other studies have reported similar results, calling into question the value of chest x-rays in surveillance settings for stage I seminomatous GCTs.^{113,115} Therefore, routine chest imaging, including chest x-ray and chest CT with contrast, should be reserved for patients with thoracic symptoms.

Follow-up After Adjuvant Treatment: Follow-up of patients treated with adjuvant therapy (chemotherapy or RT) is outlined in Table 2 on TEST-A 1 of 2 in the algorithm and includes a history and physical examination, with optional measurement of post-orchiectomy serum tumor markers performed every 6 to 12 months for the first 2 years and annually for years 3, 4, and 5. A meta-analysis of 2466 patients reported that relapse rarely

NCCN Guidelines Version 2.2022

Testicular Cancer

occurred more than 3 years after treatment with RT or carboplatin (0.2% of patients).⁷⁰ Since the rate of relapse beyond 3 years is very low for patients treated with chemotherapy or RT, the NCCN Panel recommends performing an abdominal/pelvic CT scan with or without contrast annually for the first 3 years only. An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include visualization of the retroperitoneal and pelvic nodes. Chest x-rays should be obtained only when clinically indicated, and chest CT scans with contrast should be considered for patients who are symptomatic. CT is not recommended beyond 5 years, unless clinically indicated. Relapses are treated according to the stage at relapse.⁷⁰ However, patients should not be treated based on an elevated LDH level alone.

Pure Seminoma Stage IS

Primary Treatment for Pure Seminoma Stage IS

Stage IS pure seminoma is very uncommon and requires persistent elevation of serum tumor markers following orchiectomy. Elevated tumor markers increase the risk of disease outside the retroperitoneum; therefore, systemic therapy should be encouraged. However, physicians are cautioned against treating a patient based on mildly elevated LDH or beta-hCG alone, as other causes may be responsible for elevation of these markers. Persistent elevation of serum markers is usually evidence of metastatic disease, which will show up radiographically if doubt exists in the diagnosis.

Follow-up for Pure Seminoma Stage IS

The NCCN Panel recommends repeating measurements of serum tumor markers and performing imaging studies (chest/abdominal/pelvic CT with contrast) to scan for evaluable disease.

Pure Seminoma Stages IIA and IIB

Primary Treatment for Pure Seminoma Stages IIA and IIB

Stage IIA pure seminoma is defined as metastatic disease to lymph nodes, with a lymph node mass measuring less than or equal to 2 cm in greatest diameter.¹³ A lymph node mass measuring 2 to 5 cm in greatest diameter is classified as stage IIB disease.¹³ To confirm staging before initiating treatment in select cases of stage IIA disease with borderline retroperitoneal lymph nodes, waiting 4 to 6 weeks after initial imaging assessment and repeating chest/abdominal/pelvic CT scans with contrast may be considered.

Options for the primary treatment of stage IIA and IIB seminomas include RT or chemotherapy with three cycles of bleomycin, etoposide, and cisplatin (BEP) or four cycles of etoposide and cisplatin (EP).¹¹⁶⁻¹¹⁸ If chemotherapy is given, both EP and BEP are preferred regimens in this setting. However, a bleomycin-free regimen should be considered in patients with reduced or borderline GFR, in patients older than 50 years, and in patients with chronic obstructive pulmonary disease (COPD) or other lung disease resulting in reduced pulmonary function. Different studies have reported different outcomes with regard to whether chemotherapy or RT is more effective in this setting. Two studies used data from the National Cancer Database to assess survival outcomes according to treatment strategy in patients with stage IIA/B seminoma. A retrospective study by Glaser et al compared RT with multi-agent chemotherapy in 1772 patients with stage IIA–C seminoma treated with orchiectomy.¹¹⁹ After a median follow-up of 65 months, 5-year OS was significantly higher with RT compared to chemotherapy in patients with stage IIA seminoma (99% vs. 93%; HR, 0.28; 95% CI, 0.09–0.86; $P = .027$). However, no significant difference in 5-year OS was seen in patients with stage IIB seminoma treated with post-orchietomy RT or chemotherapy (95.2% vs. 92.4%). A similar study by Paly et al evaluated data from the same database during the same time period and reached

NCCN Guidelines Version 2.2022

Testicular Cancer

similar conclusions. This retrospective, non-randomized study evaluated 1885 patients with stage IIA/B seminoma selected to receive either adjuvant chemotherapy or adjuvant RT.¹²⁰ Receipt of adjuvant chemotherapy was associated with decreased 5-year OS in patients with stage IIA seminoma (HR, 13.33; $P < .01$), but not in patients with stage IIB seminoma (HR, 1.39; $P = .45$). These studies were not randomized trials and treatment decisions were based on the treating physician's clinical judgment, which presumably was influenced by the specific characteristics of each patient. Therefore, it is possible that patients with more extensive disease were selected for chemotherapy. Nevertheless, these studies provide some support for the use of RT over chemotherapy to treat stage IIA seminoma. In contrast, a study by Mortensen et al evaluating 363 patients with stage II–III seminoma reported that the relapse rate was 6% among patients treated with chemotherapy compared to 12.6% among those treated with RT. It should be noted that chemotherapy was used for more advanced stage disease than RT in this study.⁸¹ This has led some physicians to prefer chemotherapy for patients with stage II seminoma; however, these results must be interpreted with caution since this study was not a randomized trial and did not specifically compare the two treatment modalities for stage IIA disease. Therefore, the NCCN Guidelines recommend either RT or chemotherapy as primary treatment for both stage IIA and IIB seminoma.^{118,121} However, for patients with stage IIB seminoma, RT should be reserved for select patients with non-bulky (≤ 3 cm) disease.¹¹⁶

The target fields for RT for stage IIA/B disease should include the para-aortic and proximal ipsilateral iliac lymph nodes. Treatment is delivered in two consecutive anteroposterior-posteroanterior (AP/PA) phases with no break in between. The initial phase consists of treatment of modified dog-leg fields at a dose of 20 Gy delivered in 10 fractions of 2.0 Gy each or 25.5 Gy delivered in 17 fractions of 1.5 Gy each. The panel prefers modified dog-leg fields as described by Classen et al.¹¹⁶ The second

phase (cone down) consists of daily 1.8- to 2-Gy fractions to a cumulative total dose of 30 Gy for patients with stage IIA seminoma and 36 Gy for patients with stage IIB seminoma.¹¹⁶ Prophylactic mediastinal RT is not indicated for the management of stage II disease.¹²² For details on field arrangement, see *Principles of Radiotherapy for Pure Testicular Seminoma* in the algorithm.

Follow-up for Pure Seminoma Stages IIA and Non-bulky IIB After Primary Treatment

The recommended follow-up schedule for patients with stage IIA and non-bulky stage IIB seminoma after RT or chemotherapy is outlined in Table 3 on TEST-A 2 of 2 in the algorithm and includes a history and physical examination with optional measurement of post-orchietomy serum tumor markers, performed every 3 months for year 1 and then every 6 months for years 2 through 5.

An abdominal/pelvic CT scan with contrast is recommended at 3 months and at 9 or 12 months for year 1; annually for years 2 and 3, and then as clinically indicated for years 4 and 5. An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include visualization of the retroperitoneal and pelvic nodes. CT is not recommended beyond 5 years, unless clinically indicated. Chest x-ray is recommended every 6 months for the first 2 years only. Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in the presence of thoracic symptoms.

Pure Seminoma Stages IIC and III

Primary Treatment for Pure Seminoma Stages IIC and III

Patients with stage IIC or stage III seminomas are classified as either good or intermediate risk. All stage IIC and stage III seminomas are considered good risk except for stage IIIC disease, which involves non-pulmonary visceral metastases (eg, bone, liver, brain) and is considered

NCCN Guidelines Version 2.2022

Testicular Cancer

intermediate risk. Standard primary chemotherapy is used for both groups of patients.

For good-risk patients, three cycles of BEP or four cycles of EP are recommended (both preferred).¹²³⁻¹²⁵ The two regimens have not been compared head-to-head in patients with seminoma, so the panel recommends that a number of factors be considered in choosing between the two. The specific schedule of the two regimens is different (9 weeks for three cycles of BEP compared to 12 weeks for four cycles of EP), which may make one more convenient for certain patients. While etoposide and cisplatin are associated with a dose-dependent increased risk of secondary cancers, there are no data addressing whether the risk is significantly higher with four cycles than with three. Bleomycin, which is cleared by the kidneys, is associated with a risk of pneumonitis and diminished pulmonary function. Therefore, four cycles of EP are generally preferable in patients with a reduced GFR (who would be expected to clear bleomycin more slowly), in patients older than 50 years (since renal function decreases with age), and in patients with COPD or other lung disease resulting in significantly diminished pulmonary function. Some oncologists prefer four cycles of EP for heavy smokers regardless of lung function. The different risks associated with each regimen may lead individual patients to prefer one regimen over the other. The physician and patient should make a shared decision informed by patient clinical characteristics and preferences.

For patients with intermediate-risk disease, more intensive chemotherapy with four cycles of BEP (preferred) or four cycles of etoposide, mesna, ifosfamide, and cisplatin (VIP) is recommended.¹²⁶⁻¹³¹ VIP should be reserved for patients with a contraindication to bleomycin (ie, a reduced or borderline GFR, aged >50 years, COPD, or other lung disease). All of these chemotherapy options are category 1 recommendations except for VIP, which is a category 2A recommendation.

Management of Pure Seminoma Stages IIA, IIB, IIC, and III After Chemotherapy

After primary treatment with chemotherapy, patients with stage IIA, IIB, IIC, or III seminoma should be evaluated by CT scan with contrast of the chest, abdomen, and pelvis as well as measurement of serum tumor markers. Patients with normal serum AFP and beta-hCG levels and either no residual mass or a residual mass less than or equal to 3 cm should undergo surveillance as described in Table 3 on TEST-A 2 of 2 in the algorithm and discussed in the section above on *Follow-up for Pure Seminoma Stages IIA and Non-bulky IIB After Primary Treatment*.

Surveillance is also recommended for patients with a residual mass greater than 3 cm and normal serum AFP and beta-hCG levels. A PET/CT scan from skull base to mid-thigh can be considered to better delineate the presence of viable residual tumor since CT alone cannot discriminate between residual neoplastic lesions and necrotic or fibrotic tissue.¹³²⁻¹³⁶ PET can provide useful metabolic information on these lesions, which may aid in the early detection of recurrent disease in patients with normal CT findings, since functional abnormalities usually precede morphologic ones.¹³⁶ However, testicular GCTs are typically slow-growing and have low uptake of 18-fluorodeoxyglucose (FDG) on PET scans, often resulting in unclear images of testicular lesions.¹³⁷ Additionally, the abdomen and retroperitoneal space are sites of non-specific FDG uptake, which can lead to false-positive results.¹³⁷ Possible sources of false-negative results include small malignant lesions (<3 cm) and lesions with low proliferative indices.¹³⁶ Therefore, accurate interpretation of PET scans is paramount and possible positive findings should be corroborated with the corresponding CT results. PET/CT is not indicated for residual masses less than or equal to 3 cm due to its low diagnostic accuracy in small tumors.¹³⁶ To reduce the incidence of false-positive results due to inflammation, the PET/CT scan should be performed at least 6 weeks after the completion of the last cycle of chemotherapy in patients with a residual

NCCN Guidelines Version 2.2022

Testicular Cancer

mass greater than 3 cm and normal serum tumor marker levels.^{136,138} A negative PET/CT following chemotherapy is very reassuring. If the PET/CT is negative, surveillance is recommended as described in the next section on *Follow-up for Pure Seminoma Bulky Stage II and Stage III After Chemotherapy*. If results are indeterminate, the PET/CT or CT scan should be repeated in 6 to 8 weeks. If the PET/CT is positive, resection or interventional radiology (IR)-guided biopsy of the residual mass should be considered. An alternative strategy is to repeat PET/CT scan in 8 to 12 weeks to assess for changes. If the mass is persistently FDG-avid on PET/CT, then resection or biopsy is recommended. If PET/CT is still indeterminate, CT scan or biopsy are recommended.

If the residual disease is completely resected and histopathology shows viable seminoma, two cycles of adjuvant chemotherapy can be considered with the following regimens: EP, TIP (paclitaxel, ifosfamide, cisplatin),¹³⁹ VIP, or Velp (vinblastine, mesna, ifosfamide, cisplatin).^{140,141} If the resection is incomplete and the pathology shows viable seminoma, or if there is progressive disease (growing mass or rising markers), a full course of second-line chemotherapy (four cycles of TIP or four cycles of Velp; both preferred) is recommended.¹³⁹⁻¹⁴² In rare cases, nonseminomatous elements may be identified in the biopsy specimen. If these elements are non-teratomatous, then management should proceed in the same fashion as for viable seminoma. Following adjuvant or second-line chemotherapy, patients should undergo follow-up as discussed in the next section. Patients should also adhere to this follow-up schedule if their biopsy results are negative for viable seminoma.

Follow-up for Pure Seminoma Bulky Stage II and Stage III After Chemotherapy

The recommended follow-up schedule for patients with bulky stage II or stage III seminoma after treatment with chemotherapy is outlined in Table 4 on TEST-A 2 of 2 in the algorithm and includes a history and physical

examination as well as measurement of serum tumor marker levels every 2 months for year 1, every 3 months for year 2, every 6 months for years 3 and 4, and once during year 5. Abdominal/pelvic CT scans with contrast are recommended every 4 months for year 1, every 6 months for year 2, annually for years 3 and 4, and then as clinically indicated for year 5.¹⁴³ An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include visualization of the retroperitoneal and pelvic nodes. Chest x-ray is recommended every 2 months for year 1, every 3 months for year 2, and annually for years 3 through 5. While chest x-ray may be used for routine follow-up, chest CT with contrast is preferred for patients with thoracic symptoms or residual masses or nodules in the chest. Patients with residual masses may require more frequent imaging based on clinical judgment. However, CT is not recommended beyond 5 years unless clinically indicated. Since viable tumor cells have been found in tumors greater than 3 cm with a negative post-chemotherapy PET scan,¹⁴⁴ the NCCN Panel recommends that patients with a residual mass measuring greater than 3 cm and negative PET results after chemotherapy should undergo an abdominal/pelvic CT scan with contrast every 6 months for the first year and then annually for 5 years.

Nonseminoma

Nonseminomatous GCTs include nonseminoma tumors, mixed seminoma/nonseminoma tumors, and seminoma tumors in patients with elevated serum AFP levels. To assess for metastatic disease, CT scans of the chest, abdomen, and pelvis should be performed. Use of PET/CT scan is not clinically indicated for nonseminoma.^{145,146} In select patients, brain MRI should also be performed; these patients include those with neurologic symptoms, post-orchietomy serum beta-hCG greater than 5000 IU/L or AFP greater than 10,000 ng/mL, choriocarcinoma, non-pulmonary visceral metastasis, or extensive lung metastases. Elevated levels of serum beta-hCG, LDH, or AFP should be followed up with

NCCN Guidelines Version 2.2022

Testicular Cancer

repeated tests. Repeated measurement of serum tumor markers is important because TNM staging is based on post-orchietomy values. In patients who had elevated serum tumor markers prior to orchietomy, it is important to obtain the half-life kinetics of the tumor markers after orchietomy if the markers are declining, because a slower-than-expected decline often indicates the presence of metastatic disease. The NCCN Panel emphasizes that mildly elevated, non-rising AFP levels may not indicate the presence of a GCT. Therefore, decisions to treat should not be based on AFP levels less than 20 ng/mL. Similarly, further workup should be considered before initiating treatment for mildly elevated beta-hCG (generally <20 IU/L). Sperm banking should be recommended to patients of reproductive age, if clinically indicated, before undergoing any therapeutic intervention that may compromise fertility.⁴⁰⁻⁴³

Treatment options for clinical stage I nonseminoma after inguinal orchietomy include surveillance, systemic therapy, and primary RPLND. A template dissection or nerve-sparing approach to minimize the risk of ejaculatory disorders should be considered in patients undergoing primary RPLND for stage I nonseminoma. The “split and roll” technique in which lumbar vessels are identified and sequentially ligated allows resection of all lymphatic tissue around and behind the great vessels (ie, aorta, inferior vena cava [IVC]) and minimizes the risk of an in-field recurrence. Limited data suggest increased frequency of aberrant recurrences with the use of minimally invasive laparoscopic or robotic approaches to RPLND. A recent case study of recurrence patterns in patients following robotic RPLND found that recurrences were highly variable, were in unusual locations, and were associated with a high treatment burden.¹⁴⁷ However, two retrospective reviews on robotic RPLND done at experienced centers showed that this technique can be performed safely with low complication rates and similar oncologic outcomes to an open approach.^{148,149} Therefore, minimally invasive

RPLND is not recommended as standard management, but can be considered in highly selected cases at high-volume centers.

Patients with clinical stage I pure teratoma and normal markers should receive either surveillance or RPLND. Stage II disease may be treated with systemic therapy or RPLND. Systemic therapy is preferred if serum tumor markers are elevated and/or if the enlarged lymph nodes are greater than 3 cm in greatest dimension. RPLND is preferred as primary treatment for stage II tumors with somatic-type malignancy (previously referred to as transformed teratoma), and should be considered for stage II tumors with teratoma predominance if serum tumor markers are normal. Stage II and stage III disease treated with systemic chemotherapy should be followed by surgical resection of any residual masses.

Nonseminoma Stage I Without Risk Factors

Primary Treatment for Nonseminoma Stage I Without Risk Factors

The NCCN Panel recommends treating patients with stage I nonseminoma based on the presence or absence of risk factors known to be associated with an increased risk of relapse (LVI, invasion of the spermatic cord, or invasion of the scrotum).⁴⁷⁻⁵⁵ However, regardless of risk factors, patients with stage I nonseminoma with normal post-orchietomy serum AFP and beta-hCG levels have three management options after orchietomy: surveillance,^{52,60,150,151} nerve-sparing RPLND,¹⁵² or chemotherapy (one cycle of BEP)^{153,154} as primary treatment. The major difference in the management of low-risk and high-risk patients is that surveillance is preferred for patients with stage I nonseminoma without risk factors, whereas all three management options should be carefully considered when risk factors are present. The survival rates for stage I nonseminoma managed with surveillance, nerve-sparing RPLND, or one cycle of BEP chemotherapy exceed 98%. However, the high survival rate associated with surveillance depends on adherence to periodic follow-up

NCCN Guidelines Version 2.2022

Testicular Cancer

examinations and subsequent chemotherapy for the 20% to 30% of patients who relapse. Therefore, patients who choose surveillance should adhere to the follow-up schedule. When nerve-sparing RPLND is performed, it should be done within 4 weeks of a CT scan and within 7 to 10 days of repeat serum marker testing to ensure accurate presurgical staging.¹⁵⁵ Referral to a high-volume center is recommended for nerve-sparing RPLND. Similarly, for patients electing one cycle of BEP, an abdominal/pelvic CT scan and chest x-ray or CT scan is recommended within 4 weeks prior to the initiation of chemotherapy to confirm staging, even if scans were done previously.

Management of Nonseminoma Stage I Without Risk Factors After RPLND

If the resected lymph nodes are negative for malignancy (pN0) after nerve-sparing RPLND, the patient should undergo surveillance. For positive lymph nodes (pN1 to pN3), the decision of whether to use adjuvant chemotherapy is based on the degree of nodal involvement. Surveillance is the preferred option for patients with pN1 disease, while chemotherapy is the preferred option for patients with pN2 disease (surveillance is preferred for patients with pure teratoma). Chemotherapy is the only option for patients with pN3 disease. Recommended chemotherapy regimens include two cycles of EP (preferred) for patients with pN1 or pN2 disease^{156,157} and three cycles of BEP or four cycles of EP (both preferred) for patients with pN3 disease.

Follow-up for Nonseminoma Stage I Without Risk Factors

The long-term follow-up for patients with stage I nonseminoma without risk factors includes a history and physical examination, serum tumor marker assessment, abdominal/pelvic CT scan, and chest x-ray. An MRI can be considered to replace an abdominal/pelvic CT scan. The MRI protocol should include visualization of the retroperitoneal and pelvic nodes. All

imaging in this setting is performed with contrast. The frequency of these tests varies with the primary treatment modality received by the patient (see Tables 5 and 7 on TEST-B in the algorithm). It should be noted that routine chest x-ray may have limited value for detecting relapse in patients with stage I nonseminoma. In a recent retrospective study, a total of 76 relapses were detected among 561 patients with stage I nonseminoma managed by surveillance following orchiectomy.¹¹⁴ All relapses were detected by either rising serum tumor markers and/or abnormal routine follow-up CT scans; no single relapse was detected by chest x-ray alone. Similar results have been reported in other studies, calling into question the value of chest x-rays in surveillance settings for stage I nonseminomatous GCTs.^{60,115,158} The current schedule for routine chest x-ray in the follow-up of patients with stage I nonseminoma without risk factors is two chest x-rays in year 1, one chest x-ray in years 2 through 4, and as clinically indicated in year 5 in patients managed by surveillance. Chest x-ray is not indicated in years 3, 4, and 5 for patients with stage I nonseminoma without risk factors treated with adjuvant BEP or primary RPLND.

Nonseminoma Stage I With Risk Factors

Primary Treatment for Nonseminoma Stage I With Risk Factors

Surveillance, adjuvant chemotherapy (one cycle of BEP), or nerve-sparing RPLND are the recommended primary treatment options for stage I nonseminoma patients with LVI, invasion of the spermatic cord, or invasion of the scrotum. Referral to a high-volume center is recommended for nerve-sparing RPLND. In a prospective trial by SWENOTECA, stage I nonseminoma patients with or without LVI received one course of adjuvant BEP.¹⁵⁴ The relapse rate at 5 years was 3.2% for patients with LVI and 1.6% for patients without LVI. Five-year OS was 100% in both groups.⁴⁷ The results after a median follow-up of 7.9 years confirmed the low relapse rate with one course of adjuvant BEP, especially in patients with

NCCN Guidelines Version 2.2022

Testicular Cancer

LVI.⁴⁷ Several other studies using two cycles of BEP as primary treatment for patients with stage I nonseminoma have similarly reported relapse-free survival rates of greater than 95%.^{151,157,159-162} However, late consequences of cisplatin-based chemotherapy, such as hearing damage and loss, cardiovascular conditions, hypertension, and neuropathy, have been reported during long-term follow-up.¹⁶³⁻¹⁷¹ Therefore, one cycle of BEP is recommended due to its lower toxicity. Surveillance is also a recommended primary treatment option for patients with stage I nonseminoma with risk factors. However, it should be noted that LVI is a significant predictor of relapse when orchiectomy is followed by surveillance alone.³⁵

Management of Nonseminoma Stage I With Risk Factors After RPLND

The management of patients with stage I nonseminoma with risk factors after primary RPLND is similar to that of patients with stage I nonseminoma without risk factors, as described above.

Follow-up for Nonseminoma Stage I With Risk Factors

The long-term follow-up for patients with stage I nonseminoma with risk factors includes history and physical examination, serum tumor marker assessment, chest x-ray, and abdominal/pelvic CT scan. An MRI can be considered to replace an abdominal/pelvic CT scan. The MRI protocol should include visualization of the retroperitoneal and pelvic nodes. All imaging in this setting is performed with contrast. The frequency of these tests varies with the primary treatment modality received by the patient (see Tables 6 and 7 on TEST-B in the algorithm). Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in patients with thoracic symptoms.

Nonseminoma Stage IS

Patients with stage IS nonseminoma exhibit persistent elevation of serum tumor markers post-orchietomy, but no radiographic evidence of disease. However, mildly elevated levels of AFP or beta-hCG after orchietomy must be interpreted with caution. Mildly elevated, non-rising AFP levels (<20 ng/mL) may not indicate the presence of a GCT and should not be used to guide treatment decisions. In addition, hyperthyroidism, marijuana use, hypogonadism, and heterophile antibodies can result in significant elevations of beta-hCG.^{19-21,23,24} Elevated beta-hCG due to metastatic disease typically rises steadily on serial measurements. In patients with mildly elevated but stable beta-hCG and no other evidence of metastatic disease, repeating the test using a different assay should be considered. Furthermore, many different conditions can result in an elevation of LDH, including many benign conditions. Therefore, patients should not be treated with chemotherapy for systemic disease if the only evidence of systemic disease is an elevation of LDH.

Primary Treatment for Nonseminoma Stage IS

The NCCN Panel recommends that patients with stage IS nonseminoma be treated with primary chemotherapy if the elevated marker is AFP or beta-hCG. For the purposes of this guideline, the NCCN Panel assumes that patients with stage IS disease have markers in the S1 range. It would be extraordinarily rare for a patient to have an AFP greater than 1000 ng/mL or a beta-hCG greater than 5000 IU/L and yet have no evidence of metastatic disease on imaging studies. These guidelines cannot address every possible situation, and the management of those rare patients with T any, N0, M0, S2–3 disease should be individualized; referral to a high-volume center is recommended. The vast majority of patients with stage IS have serum tumor markers in the S1 range, and they should receive primary chemotherapy for good-risk disease: either three cycles of BEP or four cycles of EP (both preferred). Both regimens are category 1

NCCN Guidelines Version 2.2022

Testicular Cancer

recommendations, and either is preferable to initial RPLND as these patients nearly always have disseminated disease.^{172,173}

Management of Nonseminoma Stage IS After Primary Treatment

The management of patients with stage IS nonseminoma after primary treatment with chemotherapy is described below in *Advanced Metastatic Nonseminoma* (see *Management of Good-, Intermediate-, and Poor-Risk Nonseminoma After Chemotherapy*).

Nonseminoma Stage IIA

Primary Treatment for Nonseminoma Stage IIA

Primary treatment for patients with stage IIA nonseminoma depends on post-orchietomy serum tumor marker levels. For patients with normal post-orchietomy levels of AFP and beta-hCG, the NCCN Panel recommends either nerve-sparing RPLND or chemotherapy with three cycles of BEP or four cycles of EP as primary treatment options (both BEP and EP are preferred regimens).^{174,175} Chemotherapy is considered particularly appropriate if the patient has multifocal disease. RPLND is preferred as primary treatment for stage II tumors with somatic type malignancy (previously referred to as transformed teratoma). Referral to a high-volume center is recommended for nerve-sparing RPLND. For patients with stage IIA seminoma with persistently elevated AFP and/or beta-hCG levels, the NCCN Panel recommends primary chemotherapy with three cycles of BEP or four cycles of EP (both category 1; both preferred).^{152,176} A bleomycin-free regimen should be given to patients at higher risk for bleomycin-related complications (ie, patients aged >50 years, those with diminished renal function, and those with underlying lung disease, etc).

Management of Nonseminoma Stage IIA After Primary Treatment

Treatment options following primary nerve-sparing RPLND include either surveillance or chemotherapy, depending on the number of positive lymph nodes identified. Since RPLND is likely a curative procedure in patients with pN0 disease, surveillance is recommended for this group. Surveillance is also the preferred option for patients with pN1 disease, although chemotherapy with two cycles of EP can also be considered.^{152,177} The risk of relapse in clinical stage IIA nonseminoma patients with pN2 or pN3 disease after RPLND is greater than 50%.^{152,178} This risk is reduced to less than 1% with two cycles of adjuvant cisplatin-based chemotherapy.^{152,179,180} Therefore, the NCCN Panel prefers two cycles of adjuvant chemotherapy with EP to surveillance for pN2 disease and recommends full-course chemotherapy (and not surveillance) for pN3 disease (either three cycles of BEP or four cycles of EP; both preferred). For patients with pathologic stage II nonseminoma, two cycles of BEP is an alternative option for those with pN3 disease following primary RPLND.¹⁸¹ A bleomycin-free regimen should be given to patients at higher risk for bleomycin-related complications (ie, patients aged >50 years, those with diminished renal function, and those with underlying lung disease). Surveillance is preferred for patients with pure teratoma.

Subsequent management after primary chemotherapy depends on the size of the residual mass on CT scan. Patients should thus undergo abdominal/pelvic CT scan with contrast within 1 month of completing chemotherapy; chest CT with contrast or chest x-ray may also be considered. Masses should be measured along the transaxial long axis (not the craniocaudal axis). If the residual mass is greater than or equal to 1 cm after chemotherapy, nerve-sparing bilateral RPLND is recommended. A bilateral RPLND involves removal of lymphatic tissue between both ureters, spanning from the diaphragmatic crus to the bifurcation of the common iliac arteries. The rationale for this extended region of dissection is the greater likelihood of bilateral disease with

NCCN Guidelines Version 2.2022

Testicular Cancer

greater tumor burden.¹⁸² Modified template RPLND may be an option in select patients with initial stage IIA/B disease within the primary landing zones. The major morbidity associated with bilateral RPLND is retrograde ejaculation, resulting in infertility. Nerve-sparing dissection techniques preserve antegrade ejaculation in 90% of cases.¹⁸³ Therefore, nerve-sparing RPLND is recommended. For patients with no residual mass or a residual mass less than 1 cm, surveillance is recommended; nerve-sparing bilateral RPLND is a category 2B recommendation in this setting and may be performed in selected cases. Referral to a high-volume center is recommended for surgical resection of masses post-chemotherapy. If only necrotic debris or teratoma is present in the resected tissue, the patient should be put under surveillance. If embryonal, yolk sac, choriocarcinoma, or seminoma elements are found in the residual mass, then two cycles of chemotherapy with either TIP, VIP, VeIP, or EP is recommended.

Follow-up for Nonseminoma Stage IIA

The 5-year follow-up for patients with stage IIA nonseminoma includes history and physical examinations, serum tumor marker assessments, chest x-rays, and abdominal/pelvic CT scans. An MRI can be considered to replace an abdominal/pelvic CT. The MRI protocol should include visualization of the retroperitoneal and pelvic nodes. All imaging in this setting is performed with contrast. The frequency of these tests varies with the primary treatment modality and post-surgical management received by the patient (see Tables 8, 9, and 10 on TEST-B in the algorithm). Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in patients with thoracic symptoms. Annual measurement of serum tumor markers can be considered for years 5 through 10 following complete response to primary chemotherapy in patients with metastatic disease.¹⁸⁴

Nonseminoma Stage IIB

Primary Treatment for Nonseminoma Stage IIB

Primary treatment for patients with stage IIB nonseminoma depends on post-orchietomy tumor marker levels and radiographic findings. When tumor marker levels are normal, the CT findings determine the proper course of treatment. If abnormal radiographic findings are limited to lymph node metastases within lymphatic drainage sites in the retroperitoneum (ie, the landing zone), patients may receive primary chemotherapy with either three cycles of BEP or four cycles of EP (both preferred) or primary nerve-sparing RPLND (reserved for highly selected cases; ie, stage II tumors with teratoma predominance in patients with normal markers). RPLND is also recommended for stage II tumors with somatic type malignancy (previously referred to as transformed teratoma). Referral to a high-volume center is recommended for nerve-sparing RPLND. Both options of primary chemotherapy or primary nerve-sparing RPLND are comparable in terms of outcome, but side effects and toxicity are different.¹⁷⁵ The reported relapse-free survival with either approach is close to 98%.^{178-180,185,186} If metastatic disease (based on radiographic findings) is not confined to within the lymphatic drainage sites (ie, multifocal or symptomatic lymph node metastases with aberrant lymphatic drainage sites), primary chemotherapy (three cycles of BEP or four cycles of EP; both preferred) is recommended. For stage IIB nonseminoma patients with persistent marker elevation, the recommended treatment option is also primary chemotherapy with either three cycles of BEP or four cycles of EP (both category 1; both preferred). A bleomycin-free regimen should be given to patients at higher risk for bleomycin-related complications (ie, patients aged >50 years, those with diminished renal function, and those with underlying lung disease).

NCCN Guidelines Version 2.2022

Testicular Cancer

Management of Nonseminoma Stage IIB After Primary Treatment

The management of patients with stage IIB nonseminoma after primary treatment with either nerve-sparing RPLND or chemotherapy is similar to the post-primary management scheme outlined above for patients with stage IIA nonseminoma (see *Management of Nonseminoma Stage IIA After Primary Treatment*).

Follow-up for Nonseminoma Stage IIB

The 5-year follow-up schedule for patients with stage IIB nonseminoma is similar to the follow-up schedule outlined above for patients with stage IIA nonseminoma and is dependent on the primary treatment modality and post-surgical management received by the patient (see *Follow-up for Nonseminoma Stage IIA* and Tables 8, 9, and 10 on TEST-B in the algorithm).

Advanced Metastatic Nonseminoma

The primary chemotherapy options for patients with advanced metastatic nonseminoma are based on the IGCCCG risk classification, which categorizes patients as good, intermediate, or poor risk based on identification of clinically independent prognostic features such as extent of disease and post-orchietomy levels of serum tumor markers.⁶⁸ When determining a patient's risk classification, the relevant serum tumor marker value is the value on day 1 of cycle one of first-line chemotherapy.

Primary Treatment for Good-Risk Nonseminoma

The IGCCCG good-risk group includes patients with stages IS, IIA (S1), IIB (S1), IIC, and IIIA disease. The treatment goal for good-risk disease is to limit toxicity while maintaining maximal efficacy. Presently, two regimens are recommended by the NCCN Panel: three cycles of BEP^{123,125,187} or four cycles of EP^{124,125,187} (both category 1; both preferred). Both regimens are well tolerated and cure approximately 90% of patients

with good-risk disease.^{187,188} The only trial that directly compared these two regimens found no statistically significant difference in OS (96% in the BEP x 3 arm vs. 92% in the EP x 4 arm; $P = .096$) or event-free survival (91% with BEP x 3 vs. 86% with EP x 4; $P = .135$).¹⁸⁷ Factors that should be considered when choosing between three cycles of BEP and four cycles of EP include the duration of treatment (9 weeks compared to 12 weeks) and regimen-specific toxicities (bleomycin is associated with reduced pulmonary function while cisplatin is associated with peripheral neuropathy and hearing loss). The physician and patient should make a shared informed decision based on patient clinical characteristics and preferences. A bleomycin-free regimen should be given to patients at higher risk for bleomycin-related complications (ie, patients aged >50 years, those with diminished renal function, and those with underlying lung disease). Some oncologists prefer four cycles of EP for heavy smokers regardless of lung function.

Primary Treatment for Intermediate-Risk (Stage IIIB) Nonseminoma

For patients with intermediate-risk disease, the cure rate is approximately 70% with the standard chemotherapy regimen of four cycles of BEP.^{189,190} Therefore, the NCCN Panel recommends four cycles of BEP (preferred), or four cycles of VIP^{189,191} for patients who are at higher risk for bleomycin-related complications, for the treatment of intermediate-risk (stage IIIB) nonseminoma. Both regimens are category 1 recommendations. However, if intermediate-risk status is based solely on LDH levels 1.5 to 3 x ULN, then 3 cycles of BEP or 4 cycles of EP¹⁹² can be considered.

Primary Treatment for Poor-Risk (Stage IIIC) Nonseminoma

The standard chemotherapy regimen for poor-risk disease is four cycles of BEP (preferred). Alternatively, four cycles of VIP can be used to treat patients who are at higher risk for bleomycin-related complications.¹⁹¹ Both regimens are category 1 recommendations. However, fewer than 50% of

NCCN Guidelines Version 2.2022

Testicular Cancer

patients with poor-risk nonseminoma experience a durable complete response to four cycles of BEP, and up to 50% die of their disease.^{68,193} Therefore, referral to a high-volume center is recommended for the management of poor-risk patients.¹⁸⁸

A recent randomized phase II trial compared the efficacy of four cycles of BEP to a more intensive regimen (carboplatin, bleomycin, vincristine, and cisplatin/BEP [CBOP/BEP]) in 89 patients with poor-risk nonseminoma.¹⁹⁴ At a median follow-up of 63 months, 3-year PFS was 56% for CBOP/BEP and 39% for BEP (HR, 0.59; $P = .079$). Three-year OS was 65% and 59%, respectively (HR, 0.79; $P = .49$), and there were no differences in toxicity between arms. The CBOP/BEP met response targets (74% complete response or partial response with negative markers) and warrants further study in a phase III trial.

Management of Good-, Intermediate-, and Poor-Risk Nonseminoma After Chemotherapy

At the conclusion of primary chemotherapy, chest/abdominal/pelvic CT scan with contrast and measurement of serum tumor marker levels are indicated to assess treatment response. PET scan has no role in assessing treatment response and residual masses following chemotherapy in patients with nonseminoma. If a complete response to chemotherapy is found by radiographic imaging and the tumor marker levels are normal, the panel recommends surveillance. Nerve-sparing bilateral RPLND can be considered in select cases for patients who had retroperitoneal lymphadenopathy prior to chemotherapy (category 2B).¹⁹⁵ RPLND is recommended within 4 weeks of the CT scan and 7 to 10 days of marker measurement. Referral to high-volume centers is recommended for surgical resection of residual masses following chemotherapy.

If there is a partial radiographic response to chemotherapy (as indicated by the presence of residual masses) and tumor marker levels are normal, then surgical resection of all residual masses is recommended.¹⁹⁶⁻¹⁹⁹ As

previously stated, referral to high-volume centers is recommended for surgical resection of masses post-chemotherapy. If only necrotic debris or teratoma is present in the resected tissue, the patient should be put under surveillance. If embryonal, yolk sac, choriocarcinoma, or seminoma elements are found in the residual mass, then two cycles of chemotherapy with either EP, TIP, VIP, or VeIP should be administered. All regimens are preferred in this setting, although EP should be considered for patients with low-volume residual disease. If there is a teratoma with somatic-type malignancy, consider histology-directed therapy and referral to a high-volume center.

Further management for patients who experience a partial radiographic response to chemotherapy (residual masses) with abnormal tumor marker levels is guided by the kinetics of the tumor markers. If tumor marker levels are elevated and persistently rising, the panel recommends a full course of second-line chemotherapy (see *Second-Line Therapy* below). Brain imaging and testicular ultrasound should be considered in patients with elevated or rising markers following primary or secondary chemotherapy to evaluate for occult brain metastases or contralateral primary disease. Patients with elevated but stable marker levels should be closely surveilled. Patients with mildly elevated and normalizing markers should be considered for surgical resection of residual masses with subsequent post-surgical management as discussed above. The panel recommends referral to a high-volume center for the management of patients with a partial response to primary chemotherapy and abnormal marker levels.

Follow-up for Good-, Intermediate-, and Poor-Risk Nonseminoma

The 5-year follow-up for patients with good-, intermediate-, and poor-risk nonseminoma after chemotherapy (with or without post-chemotherapy RPLND) includes history and physical examination, serum tumor marker assessment, chest x-ray, and abdominal/pelvic CT scan. The frequency of

NCCN Guidelines Version 2.2022

Testicular Cancer

these tests is outlined in Table 8 on TEST-B. Annual measurement of serum tumor markers can be considered for years 5 through 10 following complete response to primary chemotherapy in patients with metastatic disease.¹⁸⁴ Patients who have an incomplete response to chemotherapy require more frequent imaging than is outlined in the table. Patients who undergo RPLND and are found to have pN0 disease or pN1 pure teratoma need only one CT scan at postoperative months 3 to 4 and then as clinically indicated. An MRI can be considered to replace an abdominal/pelvic CT, and the MRI protocol should include all the nodes that need to be assessed. All imaging in this setting is performed with contrast. Chest x-ray may be used for routine follow-up, but chest CT with contrast is preferred in patients with thoracic symptoms.

Second-Line and Subsequent Therapy for Metastatic Germ Cell Tumors

Second-Line Therapy

Patients with disease relapse following first-line therapy, or those who do not experience a durable complete response to first-line therapy, should receive second-line therapy. Patients with recurrent disease who have not been treated with prior chemotherapy should be managed per their risk status, as described in the preceding sections. It is preferred by the panel that patients with recurrent nonseminoma be treated at centers with expertise in the management of this disease. Second-line therapy options for patients with early relapses (within 2 years of the completion of primary therapy) include enrollment in a clinical trial (preferred), conventional-dose chemotherapy, or high-dose chemotherapy. If chemotherapy is given, both conventional-dose and high-dose regimens are preferred in this setting. The conventional-dose regimens are TIP or VeIP.^{139,200-202} The high-dose regimens include high-dose carboplatin plus etoposide followed by autologous stem cell transplant,²⁰³ or paclitaxel plus ifosfamide followed by high-dose carboplatin plus etoposide with stem cell support.²⁰⁴

Alternatively, surgical salvage may be considered if the recurrent mass is in a solitary resectable site.²⁰⁵ Late relapses (>2 years after completion of primary therapy) occur in 2% to 3% of testicular cancer survivors.^{206,207} The panel prefers surgical salvage for these patients, if the recurrent mass is resectable.²⁰⁵ Clinical trial enrollment or chemotherapy (conventional-dose or high-dose) are options for patients with unresectable late relapses.

An ongoing, randomized, international phase III trial (TIGER) will compare second-line conventional-dose chemotherapy with high-dose chemotherapy in patients with relapsed GCTs.²⁰⁸ The foundation of the TIGER trial was formed based on the results of a large retrospective analysis by Lorch et al, which demonstrated the superiority of carboplatin-based high-dose chemotherapy compared to cisplatin-based conventional-dose chemotherapy with respect to 2-year progression-free survival (50% vs. 28%; $P < .001$) and 5-year OS (53% vs. 41%; $P < .001$).^{209,210} The TIGER trial will randomize patients with unequivocal disease progression following cisplatin-based primary chemotherapy to receive conventional-dose TIP or high-dose paclitaxel plus ifosfamide followed by high-dose carboplatin plus etoposide with stem cell support. OS is the primary endpoint. Secondary endpoints include progression-free survival, response rate, toxicity, quality of life, and biological correlates.^{208,209} This trial is currently recruiting patients and participation is highly encouraged (Clinical Trial ID: [NCT02375204](https://clinicaltrials.gov/ct2/show/study/NCT02375204)).

Management of Metastatic Germ Cell Tumors After Second-Line Therapy

To assess response after second-line therapy, a CT scan with contrast of the chest, abdomen, pelvis, and any other sites of disease is recommended. PET scan has no role in assessing treatment response and residual masses following chemotherapy in patients with nonseminoma. Levels of serum tumor markers should also be measured.

NCCN Guidelines Version 2.2022

Testicular Cancer

Patients with a complete response to second-line therapy with normal marker levels should be put under surveillance. Alternatively, select patients may receive nerve-sparing bilateral RPLND (category 2B), followed by surveillance. Referral to a high-volume center is recommended for nerve-sparing RPLND. For patients with a partial response to second-line therapy (as indicated by residual masses on CT scan) and normal marker levels, surgical resection of all residual masses is recommended followed by surveillance. If there is a teratoma with somatic-type malignancy, consider histology-directed therapy and referral to a high-volume center. Patients with a partial response to second-line therapy (residual masses) and abnormal marker levels should be managed according to the kinetics of the tumor markers. If tumor marker levels are elevated and persistently rising, the panel recommends third-line therapy (see *Third-Line Therapy* below). Patients with elevated but stable tumor marker levels should be closely surveilled. Patients with mildly elevated and normalizing markers should be considered for surgical resection of residual masses followed by surveillance. Referral to high-volume centers is recommended for surgical resection of residual masses following chemotherapy.

Third-Line Therapy

Participation in a clinical trial is the preferred treatment option for patients who experience relapse following first- and second-line therapy. Alternatively, patients previously treated with conventional-dose chemotherapy can receive high-dose regimens or be considered for surgical salvage if the recurrent mass is in a solitary resectable site. Alternative options for patients previously treated with high-dose regimens include conventional-dose salvage chemotherapy, surgical salvage (if solitary resectable site), and microsatellite instability/mismatch repair (MSI/MMR) or tumor mutation burden (TMB) testing, if disease progresses after high-dose chemotherapy or third-line therapy. The preferred treatment option for patients who experience a late relapse (>2 years after

completion of second-line therapy) is surgical salvage, if the recurrent mass is resectable. Conventional-dose or high-dose chemotherapy (if not previously received), are also options for patients with late relapse.

In order to maintain optimal efficacy and limit treatment-related toxicities, the chemotherapy regimens previously received by the patient should be considered when deciding on third-line therapy options. High-dose chemotherapy is the preferred third-line option if it has not been previously received. If high-dose chemotherapy was previously received by the patient, then palliative chemotherapy is the preferred third-line treatment option. Additionally, the panel considers pembrolizumab immunotherapy to be useful in certain circumstances (ie, in patients with MSI-high/deficient MMR [MSI-H/dMMR] or tumor mutation burden-high [TMB-H] tumors).²¹¹⁻²¹⁴

The recommended third-line palliative chemotherapy options for patients with intensively pretreated, cisplatin-resistant, or refractory GCTs are combinations of gemcitabine with paclitaxel and/or oxaliplatin,²¹⁵⁻²²¹ or oral etoposide.²²² The recommendation for gemcitabine and oxaliplatin (GEMOX) is based on data from phase II studies investigating the efficacy and toxicity of GEMOX in patients with relapsed or cisplatin-resistant GCTs.^{216,218,220} These studies showed that GEMOX is safe for patients with cisplatin-resistant testicular GCTs and may offer a chance of long-term survival.^{216,218,220} Gemcitabine and paclitaxel is another option that has shown promising results in a phase II study.²¹⁷ Follow-up results showed long-term disease-free survival in patients who progressed after high-dose chemotherapy and had not received prior paclitaxel or gemcitabine.²¹⁹ A phase II study of patients with treatment-resistant GCTs also found the combination of gemcitabine, oxaliplatin, and paclitaxel to be effective with acceptable toxicity.²¹⁵ The overall response rate was 51% with 5% of patients achieving a complete response. A second study reported similar results.²²¹ Additionally, high-dose single-agent oral etoposide was shown to be effective in a phase II study involving patients

NCCN Guidelines Version 2.2022

Testicular Cancer

who had previous treatment with cisplatin/etoposide combination regimens.²²²

Pembrolizumab, an anti-programmed cell death protein 1 (PD-1) antibody, is approved by the FDA for the treatment of patients with unresectable or metastatic MSI-H/dMMR or TMB-H solid tumors that have progressed following prior treatment and who have no satisfactory alternative treatment options.^{211,212,214,223,224} In the only trial (phase II) investigating the efficacy of immunotherapy in testicular cancer, 12 patients with nonseminoma GCTs who progressed after first-line cisplatin-based therapy and greater than or equal to one salvage regimen (high-dose or conventional-dose chemotherapy) were treated with pembrolizumab.²²⁵ Two patients achieved stable disease for 28 and 19 weeks, respectively, but no partial or complete responses were observed. There were six grade 3 adverse events, but no immune-related adverse events were reported. Therefore, pembrolizumab was well tolerated but appears to have limited single-agent activity in refractory GCTs. However, larger phase II and phase III trials of pembrolizumab in patients with metastatic or refractory testicular cancers are needed to fully assess the value of this therapy, especially in treating MSI-H/dMMR or TMB-H testicular GCTs.

Treatment of Brain Metastases

Brain metastases from testicular GCTs are relatively rare and occur almost exclusively in patients with nonseminoma histology.²²⁶ The development of brain metastases may be more common in patients with a higher burden of systemic disease; lung, liver, and/or bone metastases; high levels of serum beta-hCG (>5000 IU/L); in those with neurologic symptoms; and in those who experience relapse after cisplatin-based chemotherapy. The prognosis of patients with brain metastases from testicular GCTs is poor, with greater than 50% of patients dying within 1 year of diagnosis.^{226,227} Patients with additional adverse prognostic factors,

especially those with metachronous brain metastases, have even worse outcomes.^{226,228,229}

In a recent retrospective analysis, Loriot et al reported on the pattern of relapse among patients with poor-risk nonseminomatous GCTs previously treated with chemotherapy.²³⁰ After a median follow-up of 4.1 years, 32% were found to have radiographic evidence of brain metastases. The brain was the only site of progression in 54% of these patients and 19% experienced progression in the brain as the first progression event. Furthermore, involvement of the brain was more common among patients who were previously treated with high-dose chemotherapy (29%) compared to BEP (12%). These data suggest that brain metastases from testicular GCTs may occur more frequently than previously thought, often as the only site of progression, and may be more likely to occur in poor-risk patients previously treated with high-dose chemotherapy. However, it is unknown whether this effect was due to the lower cerebral drug penetrance of the high-dose regimen.

The optimal management of brain metastases from testicular GCTs is controversial, with a lack of evidence from prospective trials to guide treatment decisions.^{226,228} Therefore, management decisions are usually based on institutional preferences, which may in part explain the large variation in treatment modalities received by these patients. The NCCN Guidelines recommend primary cisplatin-based chemotherapy (chemotherapy for poor-risk disease) for patients with brain metastases. The addition of RT to chemotherapy regimens can also be considered.²³¹ Surgical resection of metastatic brain lesions should be performed if clinically indicated and feasible. A recent retrospective analysis reported the management of 25 patients with relapsed GCTs and progressive brain metastases who received multimodality therapy, which included high-dose chemotherapy with stem cell support alone or combined with surgery and/or stereotactic or whole-brain RT.²³² At a median follow-up of 24.5 months, 44% of patients were alive with no evidence of disease,

suggesting that this subset of patients with historically poor prognosis can potentially be cured with this approach.

Summary

The NCCN Guidelines for Testicular Cancer provide an evidence- and consensus-based treatment approach for the management of adult patients with seminomatous and nonseminomatous testicular GCTs. Testicular GCTs are sensitive to platinum-based chemotherapy and patients have high cure rates even with metastatic disease. Although the majority of metastatic testicular GCTs are cured with chemotherapy, 20% to 30% of patients will relapse after first-line chemotherapy and require additional treatment strategies. The ongoing international phase III TIGER trial aims to determine whether high-dose or conventional-dose chemotherapy is more effective in the second-line setting for patients with relapsed disease. Patients with platinum-refractory or relapsing tumors after second-line therapy have very poor outcomes despite salvage treatments with no effective alternative therapies. Targeted therapies appear to have limited activity in this setting, although more robust clinical trials are needed to assess their value in treating testicular GCTs. Prognosis for patients with brain metastases remains poor, with a lack of evidence from prospective trials to guide treatment decisions. Therefore, the NCCN Panel encourages patients with metastatic, recurrent, or platinum-refractory testicular GCTs to participate in well-designed clinical trials investigating novel therapeutic strategies to enable further advances for the management of this disease.
